Re: Site Investigation Report - Second Phase
North 1st Street Fuel Oil Terminal
Brooklyn, NY
MOSF License No. 2-1480

Dear Mr. Rubin:

The New York State Department of Environmental Conservation (the "Department") has reviewed the June 2012 Site Investigation Report, prepared by Henningson, Durham & Richardson Architecture and Engineering, P.C. (the"Report"). Soil borings were advanced at locations arranged a 60 by 60-foot grid that covered Complex A and B tank locations where more than a decade ago No.6 heating oil was stored. From each location, one surface sample and one sample with the highest PID reading were collected. At one boring location, olfactory petroleum contamination was noticeable; soil from this area was excavated and disposed of. Groundwater samples were obtained within the footprint of the tanks.

Soil analytical results for VOCs and SVOCs were compared with Table 375-6.8(a): *Unrestricted Use Soil Cleanup Objectives,* Table 375-6.8(b): *Restricted Use Soil Cleanup - Protection of Groundwater*, and with the Manhattan background data. Exceedances were noted that include elevated levels of actone, benzo(a)anthracene, benzo(b)fluoranthen, benzo(a)pyrene, chrysene ethylobenzene, indeno(1,2,3-cd)pyrene, toluene, and total xylenes.

Groundwater data were compared with TOGS 1.1.1, for the protection of drinking water (GA Class). Exceedances of the limit concentrations were revealed for most of the analyzed VOCs and SVOCs compounds.

No further action is required in relation to former MOSF No. 2-1480.

The Department has closed spill number l 112968 that was reported after a petroleum sheen had been observed at the site during demolition activities.

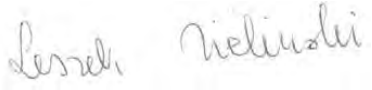
In complex A, the elevated concentrations of toluene, xylene, and acetone as well as the levels of heavy metals concentrations appear to be linked to the adjacent site, 230 Kent Avenue. Ms. Ioana Munteanu-Ramnic, the Department's project manager for remediation (V00380) conducted at 230 Kent Avenue, the former Fyn Paint and Lacquer Co., Inc. property, will review the Report in correlation with the contamination that migrated from the 230 Kent Avenue property. Ms.

Munteanu-Ramnic will contact you regarding further investigation and remediation at the former MOSF.

Gauging and sampling of monitoring wells that are solely used for the MOSF license may be discontinued.

Please call me if you have any questions concerning this letter.

Very truly yours,



Leszek Zielinski
Environmental Engineer
Division of Environmental Remediation

Re: MOSF License Closure
Con Edison of NY, Inc.
North 1st Street Fuel Oil Terminal
County: Kings
MOSF License No.: 2-1480

Dear Mr. Zielinski:

In accordance with prior arrangements for submittal of the "perimeter" investigation report, and as described in the January 2012 Site Investigation Work Plan, enclosed are two hardcopies and one CD of Henningson, Durham & Richardson's (HDR) Site Investigation Report addressing the "footprints" of the two tank complexes that were demolished earlier this year. Also enclosed is a CD containing Electronic Data Deliverables (EDD) files in NYSDEC format.

The enclosed Report is being submitted in support of Con Edison's February 27, 2012 application and letter requesting voluntary termination/permanent closure of the subject MOSF license.

NYSDEC's timely review and approval of the enclosed report is appreciated.

Please contact me at (718) 204-4219 should you have any questions or need additional information.

Very truly yours,

David B. Rubin

1. INTRODUCTION

On behalf of Consolidated Edison Company of New York, Inc. (Con Edison), Henningson, Durham and Richardson Architecture and Engineering, P.C. (HDR) has performed a Site Investigation, Second Phase, to assess subsurface conditions of the former Major Oil Storage Facility (MOSF) at the North First Street Terminal (NFST) Site. The investigation was performed in accordance with the Site Investigation Work Plan – Second Phase, prepared by HDR and dated January 2012, which was approved by New York State Department of Environmental Conservation (NYSDEC) in a letter dated January 27, 2012 (Appendix A).

1.1 Site Overview

The NFST Site is located in Williamsburg, Brooklyn, Kings County, New York (Figure 1). The NFST Site exists in a predominately mixed residential and commercial community. Historically, the Site vicinity was predominantly manufacturing but in recent years, the manufacturing community has been displaced. Residences are now located to the north, across North Third Street. Commercial and light manufacturing properties remain east of the Site across River Street from the northern portion of the NFST MOSF. At the southern portion of the NFST MOSF, a closed paint factory is to the east. A New York Power Authority (NYPA) Gas Turbine Generation Station is to the south of NFST complex. The East River is to the west of the NFST MOSF.

The NFST Site also consists of an adjacent lot on the east side of River Street, between Metropolitan Avenue and North First Street. The address of this ancillary property (boiler/control house) is 214 Kent Avenue and it is bordered by Metropolitan Avenue to the north, FYN Paint and Lacquer Co. (FYN) to the south, and River Street to the west. The ancillary property occupies approximately 0.3 acres on modern Tax Block 2362, Lot 3. Newly developed residences are east of this lot, on the opposite side of Kent Avenue, replacing light manufacturing and commercial properties that existed up until approximately 2009.

The portion of the NFST facility that is the focus of this investigation is modern Tax Block 2355, Lot 1 and Tax Block 2361, Lot 1. These lots are to the west of the control house, across River Street. Both lots contained a complex of aboveground storage tanks (ASTs). Con Edison demolished the AST complex in 2011-2012. Based on the engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; these two complexes consisted of three tanks each with the following capacities:

- Complex A (southern tanks)
    - T-100 – 6,000,000 gallons

  - T-200 – 2,325,000 gallons
  - T-300 – 6,000,000 gallons
- Complex B (northern tanks)
  - T-400 – 6,000,000 gallons
  - T-500 – 6,000,000 gallons
  - T-600 – 4,950,000 gallons

Tank construction of the two complexes was different with respect to the supporting piles. Complex A, as detailed on engineering drawings, was constructed of steel reinforced concrete, 18 inch thick slab on top of 14 –inch thin walled, cast in place 60 ton concrete piles. Complex B was constructed 18 inches of steel reinforced concrete set on top of a mixture of 60 ton, 30 ton, and 25 ton creosote timber piles that ranged from 4 to 6 feet on center. Figure 2 shows the former Site layout including the MOSF ASTs and docks, and engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; detailing Complexes A and B are included as Appendix B

1.2 Regional Geology/Hydrogeology

The Site is in the Atlantic Coastal Plain physiographic province and is comprised of interbedded layers of sand, clay and marl. The marine deposits are Cretaceous and Quaternary in age. The drift deposits are derived from glacial activity that occurred during the Pleistocene Epoch. The total thickness of the marine and glacial deposits in Kings County ranges from 0 foot in northwest Brooklyn to 1,100 feet thick in northeastern Brooklyn.

The topography of the area slopes to the west toward East River. The elevation of the Site is approximately 11 to 15 feet above mean sea level (msl). The ground surface at the Site consists of poured concrete and asphalt pavement. The shallow sediments beneath the Site consist of a brown, medium to coarse grained sand with some silt and trace gravel. In general, the subsurface beneath the area consists of interbedded layers of sand, gravel, and clay and silt mixture to approximately 75 feet below ground surface (bgs). Bedrock beneath the Site is greater than 75 feet bgs. The regional direction of groundwater flow beneath the Site is to the west, toward the East River.

1.3 Site History and Previous Investigations

Holzmacher, McLendon & Murrell, P.C. (H2M) and HDR (formerly known as Lawler, Matusky and Skelly Engineering, LLC or also known as LMS) developed background information for the Site on behalf of Con Edison. The background information presented in *Phase I Environmental Site Assessment Report – Kings County Tax No. Block 2355, Lot 1, Block 2361, Lot 1, Block 2362, Lot 3 & Block 2376, Lot 6 – 214 Kent Avenue, Brooklyn, New York* prepared by H2M and

dated September 10, 1999 and *Phase II Site Investigation Report – North First Street Oil Storage Terminal* prepared by HDR and dated January 14, 2000, is summarized below.

A Phase I Environmental Site Assessment (ESA) was performed by H2M for the Con Edison NFST property and the former Pfizer property (no longer owned by Con Edison). Based on a review of available records, a number of Recognized Environmental Conditions (RECs) were identified. These RECs included the presence of above-ground storage tanks (ASTs) and underground storage tanks (USTs) and surface and subsurface soil conditions based on historic Site usage as well as the existence of toxic or hazardous material containers.

At the request of Con Edison, HDR performed a Phase II ESA, as documented in a report dated January 14, 2000. This Site investigation encompassed the NFST Site and the former Pfizer property located to the south of the NFST MOSF facility (between East River, River Street, Grand Street and North First Street). The Phase II investigation scope included:

- Investigation and sampling of a storm drain outside one of the onsite buildings and a manhole within another, both located on the former Pfizer property. Results from both of these sample locations indicate that six semi-volatile organic compounds (SVOCs) and eleven metals were detected above the NYSDEC Technical and Administrative Guidance (TAGM) Memo #4046 - Recommended Soil Cleanup Objectives (RSCOs), which were the regulatory criteria in effect at the time of the investigation.
- Thirteen soil borings were advanced into the water table at the former oil storage area and former Pfizer site. Select samples were collected and sent to a NYSDOH certified laboratory for volatile organic compound (VOC), semi-volatile organic compound (SVOC), metals, pesticides and polychlorinated biphenyls (PCBs) analyses. Laboratory results of the soil samples indicated VOC and SVOC concentrations above the NYSDEC RSCOs. Results for the metal analyses identified ten metals with concentrations above NYSDEC RSCOs. Based on the results, no other analytes were above applicable NYSDEC RSCOs.
- Groundwater samples were collected from four monitoring wells that were initially installed onsite (MW-1, MW-2, MW-3 and MW-4) as part of the MOSF permit. Only one (MW-4) of the four monitoring wells at the Site contained VOCs concentrations in groundwater that exceeded the NYSDEC Class GA standards. Seven metals were also detected above their respective GWQS while neither SVOCs nor polychlorinated biphenyls (PCBs) were detected in the four monitoring wells.

In addition to the above two documents, a 1996 Con Edison document reported that product containing VOCs was encountered in soil borings advanced for the cathodic protection

installation associated with the Con Edison 10,000-gallon UST located in the parking lot at 214 Kent Avenue, adjoining Con Edison's MOSF boiler/control house. The VOCs detected in the product sample included toluene, ethylbenzene and xylenes totaling 876,000 milligrams per liter (mg/l). NYSDEC Spill Number 96-04977 was assigned to the contamination identified adjacent to the UST. To confirm the 1996 report, additional borings were advanced in the vicinity of the UST by HDR in 1999 to characterize the subsurface conditions in this area. This investigation concluded that free phase product was encountered and toluene, ethylbenzene and xylene were detected at elevated concentrations.

In 2001, to assess subsurface soil near the Con Edison UST, Leggette, Brashears & Graham, Inc. (LBG) conducted a limited subsurface investigation associated with the adjacent Fyn Paint facility to the south. The limited subsurface investigation consisted of installing eight soil probes utilizing direct push drilling methods and four groundwater monitoring wells using the hollow stem auger (HSA) method. Of the eight probe borings advanced, four borings were located within the Con Edison property. Three borings were advanced in the NFST parking lot (CE-1, CE-2, and CE-3), and the fourth boring was advanced along the south side of the Complex B on Metropolitan Avenue (CE-4). The rest of the probe borings were advanced outside the Con Edison Property; one was located at the west end of Grant Street (GP-1), one was located on the north side of Complex B on North Third Street (GP-2), and two were located within the Fyn Paint building (GP-3 and GP-4). Laboratory results from this investigation indicate that soil and groundwater within the NFST parking lot was impacted by acetone, ethylbenzene, toluene, and xylene. Subsurface soil concentrations at the borings advanced at NFST ranged from non detect (CE-4) to 3,200,000 micrograms per kilogram (ug/kg) of xylene at CE-1 in subsurface soils. Analytical data from Site monitoring wells in this same vicinity confirmed that these VOCs have also impacted Site groundwater. Dissolved phase VOCs were detected at concentrations ranging from non detect (CE-4) to 1,400,000 ug/l (xylene in CE-2). This information is presented in LBG's *Subsurface Investigation and Remedial Action Plan*, dated August 2001 (LBG, 2001).

To better define the limited subsurface investigation, LBG conducted Supplemental Remedial Investigations in 2003, during which all boring and wells were placed in the public right of way. In 2005, LBG expanded their supplemental investigation by installing eight additional groundwater monitoring wells and two extraction wells. VOC concentrations in subsurface soil during this investigation ranged from 19,000 ug/kg at MW-22 (acetone) to 4,000,000 ug/kg of toluene (MW-22). Groundwater concentrations ranged from non detect in CE-4 to 66,000 ug/l of toluene (EW-1). Both MW-22 and EW-1 are within the NFST parking lot. This information is presented in LBG's *Supplemental Remedial Investigation Report*, dated September 2003 (LBG, 2003).

Fyn Paint has entered into a Voluntary Cleanup Agreement under the New York State Voluntary Cleanup Program (VCP). Under this VCP, LBG installed an Interim Remedial Measure (IRM) consisting of free phase product recovery and groundwater extraction system with effluent treatment. These activities are ongoing with the treatment system inside the Fyn Paint building and extraction points at the Kent Avenue parking lot area of the Con Edison Site. The IRM will be supplemented with a dual phase extraction (DPE) system as the remediation strategy to be implemented in 2012 following approval from NYSDEC. Currently, a quarterly groundwater gauging and sampling program of a monitoring well network (Figure 3) is being implemented to assess the impacts associated with the Fyn Paint facility.

In June 2011, HDR conducted a Site Investigation to assess subsurface conditions surrounding the MOSF tanks as part of the permanent closure of tanks and associated permits. As detailed in the *Site Investigation Report – Western Portion of North First Street Oil Storage Terminal, Block 2355, Lot 1 & Block 2361, Lot 1, 49 River Street, Brooklyn, NY* prepared by HDR (July 2011), soil borings were advanced along North Third Street, River Street, North First Street and both the north and south sides of Metropolitan Avenue. Results of this "Perimeter" investigation indicated 10 of the 18 samples collected exhibited some exceedances of Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and/or Protection of Groundwater SCOs. The chemical concentrations reported in the analytical report do not appear to be indicative of a No. 6 fuel oil release from the NFST MOSF. The exceedances, for the most part, are within the same order of magnitude as the Part 375 Unrestricted Use SCOs. However, contaminants of concern from the upgradient FYN property were evident in subsurface soil at the perimeter of Complex A, as evident from the acetone concentrations detected in the B12 and B17 soil samples. The Site Investigation Report also discussed groundwater sampling results of the Fyn Paint VCP monitoring program as well as the NFST MOSF monitoring program. Figure 3 shows the locations of the monitoring wells associated with both programs. Based on the groundwater sampling results of these wells, there does not appear to be a groundwater impact associated with the MOSF.

2. SITE INVESTIGATION ACTIVITIES

To supplement the June 2011 Perimeter Subsurface Investigation, HDR conducted an additional "Footprint" investigation to assess the soils directly under the concrete footprint of the MOSF Complexes A and B. As part of this "Footprint" investigation, a surface soil assessment as well as deeper subsurface soils assessment was completed after the demolition of the tank complexes. Based on a reduced sample frequency consistent with DER-10 Section 3.9(b)(2)iii(2) and Section 1.6(c), 42 sample locations were identified in the Site Investigation Work Plan Second

Phase. This sample frequency equates to one boring per 3,600 square feet, or an approximate 60 by 60 foot grid.

2.1 Field Mobilization/Utility Clearance

Prior to the mobilization of drilling equipment HDR contracted a private utility mark-out contractor, Diversified Geophysics of Mineola, New York, to mark out utilities and other underground anomalies within the work area. Other than piles to support the former tank complexes, no subsurface anomalies were identified during the geophysical survey. Therefore, a map showing the locations of the subsurface anomalies was not prepared.

Prior to implementing any intrusive activities, a utility clearance was conducted. The procedure entailed utility mark-outs utilizing the Code 753 process, obtaining and reviewing available utility drawings and a field reconnaissance to verify, to the extent possible, the location of utilities relative to the planned intrusive locations. Aquifer Drilling and Testing, Inc. (ADT) of Mineola, NY, the drilling firm selected for the probe drilling, called in the Code 753 request.

As an added precaution and part of the Con Edison intrusive investigation program, the upper 5 feet at each soil boring was excavated using non-mechanical methods to confirm the absence of utilities (soft dig). ADT was subcontracted to perform non-mechanical clearance at each borehole location. ADT utilized hand tools (posthole digger and digging bar), an air knife, or a combination of the two methods to excavate to five feet or groundwater, whichever was encountered first. During intrusive activities, HDR screened the headspace above the excavation with a Rae Systems MultiRae combination 4-gas monitor and photoionization detector (PID). The MultiRae combination meter has a PID to monitor for total VOC vapors as well as sensors to monitor for lower explosive limits (LEL), oxygen (O_2), carbon monoxide (CO), and hydrogen sulfide (H_2S). Elevated PID readings were detected at several borings including FP B-13, FP B-13 N 5', FP B-13 E 5', FP B-13 S5', FP B-13 S 10', FP B-13 W 5', FP B-13 W 10', FP A-8, and FP A-3 during the soft dig activities (refer to Figures 4A and 4B for boring locations). During intrusive subsurface drilling activities (temporary piezometer installation), elevated PID readings were detected at FP B-11/PZ B-2, FP B-20/PZ B-3, FP-B-13/PZ B-4, FP A-3/PZ A-1, FP A-4/PZ A-2, and FP A-2/PZ A-4. All other borehole locations had background levels as measured during the field activities.

Soils were classified during soft dig activities and recorded on boring logs (Appendix C). Typically, soils above the water table consisted of silty sands with varying amounts of brick, asphalt, concrete, gravel and cobbles. Upon completion of each borehole, each hole was backfilled with the cuttings removed from that location and the location was marked with orange

flagging for future documentation of the location using Differential Global Positioning System (DGPS).

2.2 Soil Borings

To assess the subsurface conditions within the footprint of the MOSF facility, 48 vertical soil borings were advanced (Figure 4A and 4B). The objective of these borings was to physically characterize subsurface soil conditions and allow for the collection of soil samples for laboratory analysis. In the footprint of Complex B, 20 borings were advanced (FP B-1 through FP B-20) as shown on Figure 4B, and 22 borings (FP A-1 through FP A-22) were advanced within Complex A (Figure 4A). Six additional delineation borings were also advanced within the footprint of Complex B to assess the elevated PID readings noted in soils from the FP B-13 borehole. No samples for laboratory analyses were collected from the six additional delineation borings.

ADT was subcontracted by HDR to advance the soil borings using direct push technology (DPT) drilling methods and tooling. However, due to a shallow water table, DPT was not utilized to collect soil samples but was used to install temporary piezometers. In most cases, the water table was encountered during hand clearing efforts, usually within three or four feet below ground surface (bgs). All borings were advanced to the water table.

A HDR environmental scientist was on-Site during the drilling activities to log soils and collect soil samples for laboratory analyses. Soils from each boring were described in accordance with the Unified Soil Classification System (USCS) and were field screened with the MultiRae combination meter to monitor subsurface soils and headspace of the boring holes. Samples were immediately screened with the MultiRae meter to identify areas where volatile organic vapors and/or methane may be present so that samples representative of a worst case situation could be collected for analyses. Observations and field screening data from each boring was recorded on boring logs, which are included in Appendix C. A summary of the PID readings of all borings is included as Tables 1A and 1B.

In addition to the PID screening, the boreholes were also screened with the other sensors as well. No readings above background LEL concentrations (0% LEL) were noted during the investigation except at FP A-3, where an LEL of 1% was measured during advancement of direct push tooling associated with the temporary piezometer installation. Oxygen, CO, and H_2S readings from the boreholes were the same as background conditions. The readings on the other sensors were the same as background conditions during the investigation activities.

Subsurface soils observed during the subsurface investigation were described as fine to medium sands with varying amounts of silts and debris such as brick, concrete coal, ash, wood and glass. Depths to groundwater ranged from 2.5 to 6 feet bgs.

2.2.1 Soil Sampling and Analyses

As part of this "Footprint" subsurface investigation, 84 soil samples were collected from 42 soil borings. At each boring, one sample was collected from the surface and the second sample from the interval that exhibited the highest PID reading. In the absence of an elevated PID reading, the second sample was collected from the interval immediately above the groundwater table. Upon collection, samples were transferred directly into laboratory-supplied glassware. The portion of the sample collected for VOCs was transferred to the sample containers first followed by the other parameters, as needed. Each container was then labeled with the appropriate sample identification number and sample depth, the analytical parameters to be analyzed, the date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Soil samples submitted to the laboratory were analyzed for VOCs using EPA Method 8260B and SVOCs using EPA Method 8270C (base-neutral compounds only). In addition, samples from selected locations were analyzed for Target Analyte List (TAL) metals via EPA Method 6010B, pesticides following EPA Method 8081, PCBs using EPA Method 8082, and modified total petroleum hydrocarbons (TPH) following a modified EPA Method 8015. These locations were selected to provide a representation of conditions across the Site or at a borehole location that exhibited elevated PID reading and/or showed signs of contamination (odors, soil staining or sheen). Tables 2A and 2B provide the soil sample analytical summary.

Upon completion of each borehole, sampling equipment (e.g., Macrocore® sampler) was decontaminated with an Alconox and tap water wash, followed by a de-ionized or distilled water rinse. Drill cuttings that were observed to be impacted were placed in a Department of Transportation (DOT) specified drum for subsequent waste characterization sampling and off Site disposal. Soil from one borehole (FP B-13) showed some evidence of a potential impact with a heavy sheen noted on the soils. Soils from this borehole were drummed, with an estimated volume of approximately 1/3 full. One other borehole (FP A-3) showed signs of being potentially impacted. However, no excess soil from other locations was generated. At borehole locations where no evidence of a potential impact was observed, cuttings were returned to the subsurface at the location that the cuttings were generated.

The location of each boring was surveyed using a DGPS for documentation purposes. Due to the proximity of the borings to adjacent buildings/structures, there was potential that satellite signals could be disrupted, which could distort the plotted location. Therefore, on boreholes where poor satellite distribution was noted, the borehole was triangulated using two fixed points such as fire

hydrants or manholes in addition to using a DGPS. The DGPS data and triangulations were used to prepare a figure that most accurately locates each boring (Figures 4A and 4B).

2.3 Temporary Piezometer Installations

ADT was subcontracted by HDR to advance soil borings and install temporary piezometers at select locations within the footprint of the MOSF tanks. These temporary piezometers were installed using DPT drilling methods and tooling. All borings were advanced continuously in five-foot increments using a 2-inch diameter Macrocore® barrel with dedicated PVC liners. Each borehole was advanced into the water table. HDR installed 9 temporary piezometers within the footprint of the former tank complexes to assess the groundwater conditions beneath the tank farm (Figures 5A and 5B). Each piezometer was offset slightly from the boring location to avoid collecting an excessively turbid groundwater sample which could bias the analytical results. Five piezometers were installed in Complex A and 4 piezometers were installed in Complex B. An HDR environmental scientist was on-Site during the drilling activities to observe the installation process and to log the boreholes. Consistent with the soil borings, subsurface soils observed during the temporary piezometer installations were described in accordance with the Unified Soil Classification System (USCS). Soils collected from borehole advancement were also field screened with a MultiRae meter to monitor subsurface conditions. Observations and field screening data from each boring was recorded on boring logs, which are included in Appendix D.

Upon reaching the termination depth for each borehole, a 10 foot length of 1 inch diameter polyvinyl chloride (PVC), 0.002 inch slot screen was placed in the borehole such that the screened section of each piezometer intersects the water table. Piezometer construction logs documenting the construction details are included as Appendix E and a summary of temporary piezometer construction details is provided on Table 3. Following installation of the temporary piezometers, the groundwater was allowed to equilibrate to near steady state conditions. Once steady state conditions were obtained, the groundwater within the piezometer was gauged with an oil water interface probe to the nearest one-hundredth of a foot to provide a depth to water (DTW) measurement and/or a depth to product (DTP) measurement, if free phase product was encountered. Measurements were recorded from the surrounding ground surface and are included in Appendix F. Groundwater depths ranged from 2.25 feet bgs to 5.85 feet bgs. No measurable free product was encountered in any of the piezometers during this investigation.

2.3.1 Groundwater Sampling and Analyses

As part of this "Footprint" subsurface investigation, one groundwater sample was collected from each of the 9 temporary piezometers; five samples from Complex A and four samples from Complex B.

Upon completion of groundwater gauging, dedicated ¼ inch, inside diameter (ID) low density polyethylene (LDPE) tubing was placed into each temporary piezometer and connected to a variable speed peristaltic pump utilizing laboratory-grade silicone tubing. The piezometers were then purged of approximately 0.33 ounces to 3 gallons (gal) of water in an effort to collect turbid free samples. Purged water was collected in a five gallon pail and was assessed using olfactory senses for impacts for subsequent disposal.

Once turbid free conditions were reached, groundwater samples were collected directly into laboratory supplied glassware. Each container was then labeled with the appropriate sample identification number, parameters to be analyzed, date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Purge water was determined to be free of visible contamination (free phase product or heavy sheen) and was then discharged back into the borehole from which it was purged following sample collection.

All groundwater samples were analyzed for VOCs using EPA Method 8260B, SVOCs using EPA Method 8270C (base-neutral compounds only). Also, a sample from PZ A-1 (FP A-3) was analyzed for PCBs using EPA Method 8082 and modified Total Petroleum Hydrocarbon (TPH) following a modified EPA Method 8015, based on the presence of a heavy sheen and elevated PID readings that were noted during borehole advancement.

2.4 Review of MOSF and FYN VCP Groundwater Monitoring Data

In addition to the subsurface soil and groundwater evaluation, six years of MOSF compliance sampling data and three years of Fyn Paint and Lacquer Company, Co. groundwater remediation data were also evaluated as part of this Investigation. This information was previously summarized in the June 2011 Site Investigation Report, but is updated herein considering the groundwater data collected since that investigation. Monitoring well locations associated with the Con Edison MOSF and the Fyn Paint VCP are shown on Figure 3. A summary of the monitoring well construction details is provided on Table 4. A discussion of the analytical results is provided below.

2.4.1 North 1st Street Major Oil Storage Facility Data (MOSF)

As part of the MOSF annual sampling program, four monitoring wells located in proximity to the tank farm were gauged on a monthly basis and sampled on an annual basis. These wells are identified as NTMW-1, NTMW-2, NTMW-3, and NTMW-4, (also referred to as MW-1 through MW-4). Under the MOSF requirements, the samples from these wells were analyzed for SVOCs only, but due to the litigation associated with the Fyn Paint facility, VOCs were subsequently added. Data dating back approximately to 2001 shows that the samples were regularly analyzed for VOCs and SVOCs using EPA Methods SW8260B and SW8270C with some analytes being analyzed using EPA 624/8260B and EPA 625/8270C. In 2007, SVOCs were analyzed using EPA Method SW8270B. Only selected analytes were reported in 2011 using EPA Method SW8021 for VOCs and EPA Method SW8270C for SVOCs. The groundwater samples collected in March 2012 were not submitted for SVOC analyses. Groundwater analytical data for NFST MOSF wells is provided on Table 5.

NTMW-1, installed as a stick-up protective casing well at the west end of Metropolitan Avenue between the two tank farms, had detections of acenaphthene (0.48 ug/l) and anthracene (0.03 ug/l) during the March of 2011 sampling event. However, no other compounds were detected in the 2010 or 2011 sampling events. Although these two compounds were detected at well NTMW-1, the concentrations are well below the most restrictive guidance value in the Division of Water Technical and Operational Guidance Series (1.1.1) (TOGS 1.1.1) of 5.3 ug/l (TOGS Class A waters) for acenaphthene and 3.3 ug/l (TOGS Class A waters) for anthracene. Similarly, toluene (2.2 ug/l) was detected in NTMW-1 in March 2012, but this concentration is below the groundwater quality standard of 5 ug/l.

MOSF Well NTMW-2 was installed with a stick-up protective casing at the west end of North First Street. Within the last two years (2010 and 2011), no VOCs or SVOCs were detected at concentrations above their associated detection limits at MOSF Well NTMW-2. No VOCs were detected in the sample collected from NTMW-2 in March 2012.

MOSF well NTMW-3 was installed with flush mount surface completion near the west end of North Third Street. Analyses of a sample collected from NTMW-3 showed no compounds were detected in the March 2010 sampling event. However, in March of 2011, several SVOCs were detected. These compounds are summarized in Table 5. NTMW-3 is located between the oil storage facility and a new apartment building, in a publicly accessible area. Due to the street cleaning, snow clearing and potentially public access, the well had been compromised. Construction associated with the redevelopment of North 3rd Street and the new apartment building has further damaged the monitoring well. The well was subsequently closed in accordance with New York State Department of Environmental Conservation procedures in

November 2011 due to its being compromised. These detections are possibly the result of stormwater runoff entering the compromised well.

NTMW-4 was installed as a flush mount well within the sidewalk along the west side of River Street between Metropolitan Avenue and North First Street. It is the closest MOSF monitoring well to the Fyn Paint and Lacquer building. Several VOCs have been detected in the samples collected from this monitoring well over the past two years. No SVOCs were detected above detection limits in either the March 2010 or March 2011 sampling events. In March 2012, three chlorinated VOCs (chlorobenzene at 5.9 ug/l, cis-1,2-dichloroethene at 3.4 ug/l, and 1,1-dichloroethane at 3.9 ug/l) were detected in this well. However, only the chlorobenzene concentration was above the groundwater quality standard.

2.4.2 Fyn Paint and Lacquer Site

The Fyn Paint VCP groundwater monitoring program currently consists of quarterly sampling of up to 30 wells and piezometers for VOCs. However, several wells were subsequently removed or reduced to annual sampling from the Fyn Paint monitoring program due their distance from the Fyn Paint contamination source. Because of the proximity of these Fyn Paint wells to the MOSF, the data set was reviewed to assess groundwater conditions within the NFST MOSF vicinity. Of the wells monitored as part of the Fyn Paint VCP, nine wells are immediately adjacent to the NFST MOSF. In addition to the four Con Edison MOSF wells (NTMW-1 through NTMW-4), these nine wells also include MW-10, MW-12, MW-14, GP-2, and CE-4. Although quarterly groundwater samples collected as part of the Fyn Paint VCP investigation date back to February 2008 and seven sporadic groundwater sampling events occurred from September 2001 through March 2007, only the data collected from the first quarter 2009 through first quarter 2012 are summarized herein. Groundwater analytical data for Fyn Paint VCP wells adjacent to the MOSF wells is provided on Table 6 and a summary of all Fyn Paint VCP wells is included as Appendix G.

Over the past three years, approximately 275 groundwater samples were collected for the Fyn Paint VCP, excluding quality control samples, and analyzed for VOCs following EPA Method 8260. VOCs are the primary contaminants of concern associated with the Fyn Paint site and several VOCs were detected at concentrations in excess of TOGS 1.1.1 Groundwater Quality Standards (GWQS). The predominant Fyn Paint contaminants of concern - acetone, benzene, toluene, ethylbenzene, and total xylenes - were detected most frequently and at the highest concentrations of the VOCs.

Acetone was detected at levels above the GWQS of 5 ug/l in eight Fyn Paint VCP wells: ASW-1 (sampled one time only), EW-1, MW-15, MW-16, MW-21, MW-22, MW-24, and MW-28.

None of these wells are adjacent to the NFST MOSF. Concentrations ranged from 11 ug/l in the MW-24 sample (2nd quarter 2011) to 800,000 ug/l in the MW-28 sample (2nd quarter 2010). In general, concentrations have fluctuated from event to event with the lowest average concentrations being detected in November 2009. According to the LBG report, the decrease noted between June 2010 and September 2010 can be attributed to the start-up of the groundwater pump and treat system at the end of August 2010. However, the variation in concentrations may also be attributed to other factors such as seasonal fluctuations, sampling methods, or hydrogeologic factors. Acetone is not a constituent of fuel oil. It is known to have been used at the Fyn Paint facility.

In both the MOSF and Fyn Paint VCP wells, benzene concentrations in the groundwater samples range from 1.3 ug/l reported in February 2009 at MW-8 to 360 ug/l reported in September 2010 at MW-13. Benzene was also detected in 11 additional wells over the course of the thirteen sampling events: EW-1, GP-1, MW-4, MW-6, MW-9A, MW-10, MW-15, MW-16, MW-21, MW-24, and MW-28, each of which is associated with the Fyn Paint VCP. With the exception of MW-10, these wells are either cross gradient or upgradient of the MOSF. The benzene concentration detected in MW-10 was 2.2 ug/l, during the second quarter of 2010. Benzene was not detected in this well during the 12 other quarters in this three year period. Based on the distribution of the benzene concentrations, the source of the benzene is likely an off-Site source or sources.

For the Fyn Paint VCP investigation, toluene concentrations ranged from 2.6 ug/l at MW-8 in June 2010 to 430,000 ug/l at MW-13 in March the 3rd quarter of 2011. Toluene was detected in 155 samples with 151 sample concentrations exceeding the GWQS of 5 ug/l. A general comparison of the concentration detected during the sampling events indicates a slight increase of toluene in the groundwater quality samples over this timeframe. Of the wells immediately adjacent to the MOSF, toluene was most frequently detected in the sample collected from MW-12 with the highest concentration (13,000 ug/l) detected in May 2009. Over the past three years, the samples collected from MW-4 in February 2010 (30 ug/l), from MW-10 in June 2010 (1,100 ug/l) from MW-14 in December 2011 (29 ug/l), MW-20 in September 2010 (30 ug/l), and from CE-4 in December 2009 (42 ug/l) were the only other wells immediately adjacent to the MOSF that showed detections for this compound. Considering the toluene distribution, the MOSF does not appear to be a source of this compound.

For the Fyn Paint VCP investigation, the concentrations of ethylbenzene range from 2.1 ug/l as reported at MW-10 in December 2010 to 34,000 ug/l at MW-22 in September 2011. Of the 147 samples where ethylbenzene was detected, 135 concentrations exceeded the GWQS of 5 ug/l. Of the wells immediately adjacent to the MOSF, ethylbenzene was most frequently detected in

MW-12, with the highest concentrations (15,000 ug/l in May 2009 and March 2010). Ethylbenzene was also detected in 4 other wells, MW-4 (high of 150 ug/l, March 2010), MW-10 (high of 1,100 ug/l, June 2010), MW-20 (high of 19 ug/l, September 2010) and CE-4 (detected only once in March 2011 at 16 ug/l).

The overall concentrations of total xylenes have been decreasing on average over the last two years though the number of detects per sampling event have risen indicating that the concentration of xylenes in the groundwater is becoming more dispersed over time. Total xylenes have been detected above the GWQS of 5 ug/l in 176 of the 275 samples collected. A maximum concentration of 144,000 ug/l was detected at MW-22 in September of 2011 and the lowest detected concentration of 2.1 was recorded at MW-27 in March of 2011.

Eleven other compounds were also detected at concentrations exceeding the GWQS in wells adjacent to the MOSF include 2-butanone, chlorobenzene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,1-dichloroethane, 1,2-dichlorobenzene, isopropylbenzene, 1,2,3-trichloropropane, trichloroethene, vinyl chloride, and tetrahydrofuran. None of these compounds are associated with fuel oil. The source of these compounds is unclear although documentation exists regarding Fyn Paint's use of 2-butanone.

Naphthalene, a common constituent of fuel oils, was not detected in any of the groundwater samples collected over this three year period.

2.5 Review of Soil Gas Sampling Data

In addition to groundwater results, historic soil vapor data associated with the Fyn Paint VCP were also evaluated. As part of the Fyn Paint VCP, the nearest soil gas point to the MOSF was installed at the northwest corner of North First Street and River Street. Based on the results of a soil gas sample collected from that point indicated 1,1,1-trichloroethane (TCA) was present in the soil vapor at a concentration of 680 micrograms per cubic meter ($\mu g/m^3$), as presented in LBG's *Soil Vapor Intrusion Investigation Work Plan* (LBG, 2007). Under the New York State Department of Health Guidance for Vapor Intrusion, TCA concentrations in sub-slab samples are actionable for monitoring or mitigation at 100 $\mu g/m^3$. TCA is not a component of No. 6 fuel oil, but is a solvent used in inks, paints, adhesives and other coatings.

3. ANALYTICAL RESULTS DISCUSSION

3.1 Soil Boring Results

The analytical results of the samples collected during the 2012 "Footprint" Investigation were compared to NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and

Protection of Groundwater SCOs. Based on the laboratory analytical results of the 84 samples (42 surface, and 42 subsurface samples), the soils across the Site generally appear consistent. However, exceedances of some of the above SCOs are reported. A summary of the number of samples with one or more SCO exceedances is presented in the following table (Manhattan Background concentrations for SVOCs and metals are also listed for comparative purposes).

Sample Parameter	No. of Samples Collected	Unrestricted Use SCO	Protection of Groundwater SCO	Manhattan Background
VOCs	84	11	11	NA
SVOCs	84	35	30	15
Pesticides	17	7	0	NA
PCBs	17	3	0	NA
Metals	17	17	4	3

Figures 6A, 6B, 7A, 7B, and 8A, 8B show the locations with exceedances of the Unrestricted Use, and Protection of Groundwater SCOs as well as compared to Manhattan Background soil concentrations (The RETEC Group, 2007) for Complex A and Complex B. A summary of the surface soil analytical results with comparison to the Unrestricted land use SCOs is presented in Tables 7A and 7B. Tables 8A and 8B provides a summary of the subsurface analytical results in comparison to the Unrestricted land use SCOs. A summary of surface soil analytical results in comparison to Protection of Groundwater SCOs is presented in Tables 9A and 9B. Tables 10A and 10B provide a summary of subsurface soil analytical results in comparison to Protection of Groundwater SCOs. Tables 11A and 11B provide a summary of surface soil analytical results in comparison to Manhattan Background, and Tables 12A and 12B provide a summary of subsurface soil analytical results in comparison to Manhattan Background concentrations. The complete analytical data packages are included as Appendix H.

3.1.1 Complex A

As part of this investigation, 22 borings were advanced within the "Footprint" of the MOSF at Complex A. One surface sample (22 total samples) and one subsurface sample (also 22 total samples) were collected from each location. Samples were analyzed at a NYSDOH certified lab for VOCs and SVOCs. From select locations, samples for pesticides, PCBs, and TAL metals analyses were also collected. If elevated PID readings or visual signs of contamination were noted, a modified TPH analysis was also requested. Analytical results were compared to Unrestricted Use SCO, Protection of Groundwater SCOs, and Manhattan Background

concentrations. A summary of the analytical results are included as Table 7A, 8A, 9A, 10A, 11A, and 12A, and a graphic summary is included as Figure 6A, 7A, and 8A.

Eleven out of the 22 surface samples collected have concentrations above Part 375 Unrestricted Use SCOs. Six samples contained VOC exceedances, four samples contained SVOC exceedances, five samples contained metal exceedances, one sample exceeded for pesticides and one sample exceeded for PCBs.

Acetone was the only VOC detected at concentrations greater than the Unrestricted Use SCO of 50 ug/kg. Analytical results of acetone ranged from 51 ug/kg to 220 ug/kg. No other VOC compounds were detected at concentration in excess of their respective SCO.

Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene were the only SVOCs detected at concentrations above their respective Unrestricted Use SCOs. In the surface samples, concentrations of these PAH compounds ranged from 620 ug/kg (indeno(1,2,3-cd)pyrene) in borehole FP A-17 SUR to 1,800 ug/kg (benzo(b)fluoranthene) in FP A-4 SUR.

Concentrations of five metal compounds (chromium, copper, lead, zinc, and mercury) exceed their respective Unrestricted Use SCOs in the surface samples. Chromium was detected in all five samples where Unrestricted Use SCOs were exceeded. Concentration of chromium ranged from 10.4 ug/kg (FP A-21 SUR) to 26.8 ug/kg in samples FP A-4 SUR. Lead and zinc were detected in 3 samples (FP A-1 SUR, FP A-4 SUR and FP A-15 SUR) at concentrations above the Unrestricted Use SCOs. Lead concentrations ranged from 106 mg/kg in FP A-1 SUR to 181 mg/kg in FP A-15 SUR above the Unrestricted Use SCO of 63 mg/kg. Zinc concentrations ranged from 131 to 179 mg/kg, above the Unrestricted Use SCO of 109 mg/kg. Copper and mercury were detected above the Unrestricted Use SCO in 2 samples each. Copper was detected above the Unrestricted Use SCO of 50 mg/kg in samples collected from FP A-1 SUR (62.2 mg/kg) and FP A-15 SUR (67.9 mg/kg). Both exceedances are on the same order of magnitude as the SCO. Mercury was also detected in 2 samples collected (FP A-15 SUR and FP A-21 SUR). Concentrations ranged from 0.29 mg/kg to 0.98 mg/kg, above the Unrestricted Use SCO of 0.18 mg/kg.

Pesticides and PCBs were also detected above Unrestricted Use SCO in one sample (FP A-4SUR). Pesticide concentrations were on the same or one order of magnitude above the respective SCO. Concentrations of 4,4'-DDD, 4,4'-DDT and dieldrin were detected above the Unrestricted Use SCOs of 3 ug/kg, 3 ug/kg, and 5 ug/kg respectively. Concentrations ranged from 7.1 ug/kg (dieldrin) to 19 ug/kg (4,4'-DDT). Aroclor 1254 was the only PCB that was detected. The Aroclor 1254 concentration detected was 220 ug/kg, which is above the Unrestricted Use SCO of 100 ug/kg (for total PCBs).

At Complex A, the surface sample that appears to be most impacted was collected at FP-A-4, where VOCs, SVOCs, pesticides, PCBs and metals concentrations all exceeded the Unrestricted Use SCOs.

Results of the subsurface samples show exceedances of the Unrestricted Use SCOs at nine locations: FP-A-3, FP-A-8, FP-A-13, FP-A-15, FP-A-16, FP-A-17, FP-A-20, FP-A-21, and FP-A-22. VOCs exceeded the Unrestricted Use SCO at FP-A-3 and FP-A-15. At FP-A-3, concentrations of ethylbenzene, toluene and total xylenes were above the Unrestricted Use SCOs of 1,000 ug/kg, 700 ug/kg, and 260 ug/kg, respectively. At FP-A-15, the acetone concentration (55 ug/kg) exceeded the Unrestricted Use SCO of 50 ug/kg.

In the subsurface samples, five of twenty-two samples were reported to have SVOC concentrations exceeding the Unrestricted Use SCOs. The SVOCs with concentrations exceeding the Unrestricted Use SCOs are PAHs, specifically benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene. In general, the concentrations of these compounds were an order of magnitude above the Unrestricted Use SCOs. However, not all compounds exceeded the Unrestricted Use SCOs in each of the five samples. The sample collected from FP-A-16 appears to have the highest SVOC concentrations detected.

Metal concentrations exceeded the Unrestricted Use SCOs in each of the four subsurface samples collected for metal analyses. Chromium concentrations exceeded the SCO in each sample whereas lead and mercury concentrations exceeded the SCO in two of the four samples (FP-A13 and FP-A-21). Barium, copper, and nickel exceeded the Unrestricted Use SCO in one sample only, FP-A-21. With the exception of nickel, each exceeding concentration at FP-A-21 was an order of magnitude above the cleanup objective.

PCBs and pesticides were detected at concentrations exceeding the Unrestricted Use SCOs in two of the four subsurface samples collected for these analyses (FP-A-13 and FP-A-21). At FP-A-13, 4,4'-DDT (5.9 ug/kg) and Aroclor 1254 (110 ug/kg) were detected above the Unrestricted Use SCOs of 3 ug/kg and 100 ug/kg, respectively. At FP-A-21, three pesticides, 4,4'-DDD (11 ug/kg) 4,4'-DDE (6.9 ug/kg) and 4,4'-DDT (13 ug/kg) had concentrations exceeding the Unrestricted Use SCO of 3 ug/kg for each pesticide. Concentrations of Aroclors 1254 (62 ug/kg) and 1260 (61 ug/kg) in the FP-A-21 subsurface sample were below the Unrestricted Use SCO, but the total PCB concentration of 123 ug/kg was above the 100 ug/kg cleanup objective.

With respect to the Protection of Groundwater SCOs, one VOC, three SVOCs, and one metal were reported to have concentrations that exceed the guidance in surface soil samples. Acetone

exceeded the Protection of Groundwater SCO (50 ug/kg) in six samples with the high concentration of 220 ug/kg in sample FP A-11 SUR. The other acetone Protection of Groundwater SCO exceedances were slightly over the SCO with concentrations ranging from 51 ug/kg to 63 ug/kg, on the same order of magnitude as the SCO. The three SVOCs that exceeded the Protection of Groundwater SCOs in the surface samples were benzo(a)anthracene and chrysene, both in three samples (FP A-4 SUR, FP A-7 SUR, and FP A-13 SUR) and benzo(b)fluoranthene in one sample (FP A-4 SUR). Chromium is the only metal with Protection of Groundwater SCO exceedances, occurring in two samples, FP A-1 SUR and FP A-4 SUR, with concentrations of 21.4 ug/kg and 26.8 ug/kg, respectively.

For the subsurface samples, the Protection of Groundwater SCOs were exceeded for VOCs, SVOCs, and metals. Samples with VOC exceedances include FP-A-3 (4.0-4.5) where ethylbenzene, toluene and total xylenes exceeded the criteria and FP-A-15 (4.0-4.5) where acetone exceeded the criteria. The samples with SVOC Protection of Groundwater exceedances include FP-A-16 (3.5-4.0), FP-A-21 (4.5-5.0) and FP-A-22 (3.5-4.0). The specific SVOCs that exceeded the criteria include benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene. Metals that exceeded the Protection of Groundwater SCOs include chromium in FP A-8 (4.0-4.5), and barium, chromium, lead and mercury in FP-A-21 (4.5-5.0).

The SVOC and metal analytical results were also compared to background PAH and metal concentrations in Manhattan soils in combination with the Unrestricted Use SCOs. At Complex A, there were no exceedances of both combined criteria in any of the surface soil samples. For the subsurface samples, three locations, FP-A 16 (3.5-4.0), FP A-21 (4.5-5.0), and FP A-22 (3.5-4.0), each had 7 PAHs with concentrations that exceeded both criteria. Only one subsurface sample, FP A-21 (4.5-5.0), had metals with concentrations exceeding both criteria. These metals include barium, chromium, copper, and nickel.

3.1.2 Complex B

As part of this investigation, 20 borings were advanced within the “Footprint” of the MOSF at Complex B. One surface sample (20 total samples) and one subsurface sample (also 20 total samples) were collected from each location. Samples were analyzed at a NYSDOH certified lab for VOCs and SVOCs. From select locations, samples for pesticides, PCBs, and TAL metals analyses were also collected. If elevated PID readings or visual signs of contamination were noted, a modified TPH analysis was also requested. Analytical results were compared to Unrestricted Use SCO, Protection of Groundwater SCOs, and Manhattan Background soil concentrations. Summaries of the analytical results for the surface and subsurface samples are

included as Table 7B, 8B, 9B, 10B, 11B, and 12B, and graphic summaries are included as Figure 6B, 7B, and 8B.

VOC analytical results show only one compound (acetone) with a reported concentration above the Unrestricted Use SCOs in surface soils. The acetone concentration was 51 ug/kg, above the SCO of 50 ug/kg. No other VOCs were detected in surface soil samples at concentrations exceeding the Unrestricted Use SCOs. Of the subsurface samples, only two locations, FP-B-11 3.5' and FP-B 17 4.5', had exceedances of the Unrestricted Use SCOs. In the FP-B-11 3.5' sample, concentrations of benzene (180 ug/kg), ethylbenzene (1,300 ug/kg) and total xylenes (1,600 ug/kg) exceeded the SCOs of 60 ug/kg, 100 ug/kg, and 260 ug/kg, respectively. At FP-B-17 4.5', the acetone concentration (97 ug/kg) was above the Unrestricted Use SCO of 50 ug/kg. However, this concentration was flagged with a "B", indicating it was also detected in the method blank associated with that sample.

At Complex B, concentrations of several SVOCs exceeded the Unrestricted Use SCOs. Of the 20 surface soil samples, 11 samples had one or more SVOC with concentrations exceeding the Unrestricted Use SCOs. These compounds included up to 8 PAHs, specifically benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzofuran, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene, that exceeded the Unrestricted Use SCOs. Of these compounds, benzo(b)fluoranthene and chrysene had the most exceedances (10) in the surface samples. The surface soil samples with the highest concentrations appear to be FP-B-2 S and FP-B-7 S.

For the subsurface soil samples, 15 of the 20 samples collected had SVOC exceedances above the Unrestricted Use SCOs. These individual SVOCs are the same compounds listed above for the surface soil samples. In general, the detected concentrations were on the same or one order of magnitude above the Unrestricted Use SCOs. The subsurface sample with the highest concentrations is FP-B-11 3.5', where the concentrations were generally an order of magnitude above the cleanup objectives. This subsurface sample is the only location where naphthalene was detected at a concentration exceeding the Unrestricted Use SCO. The naphthalene concentration at this location was reported at 13,000 ug/kg, above the cleanup objective of 12,000 ug/kg.

Pesticides were detected in four samples at concentrations exceeding the Unrestricted Use SCOs. These samples include two surface samples, FP-B-16 S and FP-B-17 S, and two subsurface samples, FP-B-2 3' and FP-B-20 4.5'. The specific pesticides that exceeded the Unrestricted Use SCOs include 4,4'-DDD, 4,4'-DDE, and 4,4'-DDT. The exceedances were generally on the same or one order of magnitude above the SCOs.

PCB concentrations did not exceed the Unrestricted Use SCOs in any sample collected from Complex B during this investigation. The highest detected concentration was 72 ug/kg of Aroclor 1254 in sample FP-B-20 4.5'.

Metal concentrations exceeded the Unrestricted Use SCOs in 8 surface and subsurface soil samples at Complex B. The specific metals include barium, chromium, copper, lead, mercury, and zinc. With the exception of lead and copper, the exceedances were on the same order of magnitude as the cleanup objectives. The highest detected lead concentration was 274 mg/kg in sample FP-B-17 S, above the Unrestricted Use SCO of 63 mg/kg. The highest detected copper concentration was 154 mg/kg in sample FP-B-16 S, above the cleanup objective of 50 mg/kg. No other metal concentrations exceeded the Unrestricted Use SCOs at Complex B.

Protection of Groundwater SCOs were exceeded for VOCs in three samples at Complex B. The specific VOCs include acetone in the duplicate sample of FP-B-3 S and FP-B-17 4.5' and both benzene and ethylbenzene in FP-B-11 3.5'. With the exception of the benzene concentration, the exceedances were on the same order of magnitude as the SCO. The benzene concentration was one order of magnitude above the SCO.

Five individual SVOCs were reported with concentrations exceeding the Protection of Groundwater SCOs in the surface and subsurface samples. These compounds include benzo(a)anthracene (in 22 samples), benzo(b)fluoranthene (in 12 samples), benzo(k)fluoranthene (in 3 samples), chrysene (in 24 samples), and naphthalene (in one sample). In general, the exceedances were on the same order of magnitude as the SCO. The most impacted boring with respect to this criteria is FP-B-11 3.5', where the exceedances were an order of magnitude above the SCOs.

At Complex B, there were no reported concentrations of pesticides, PCBs, or metals that exceeded the Protection of Groundwater SCOs.

A comparison of the analytical results with the Soil Background PAH and Metal Concentrations combined with the Unrestricted Use SCOs show that 12 samples have PAH exceedances and two samples have metal exceedances (see Tables 11B and 12B). The PAH exceedances are likely due to the presence of creosote treated piles spaced 4 to 6 feet apart throughout Complex B. The two samples with metal exceedances are samples of FP-B-16S and FP-B-17S, where barium, copper and zinc concentrations were greater than the criteria. The barium concentration at FP-B-17S is 425 mg/kg versus the background concentration of 248 mg/kg. For copper at FP-B-16S, the detected concentration was 154 mg/kg, above the background concentration of 141 mg/kg. Zinc concentrations exceeded the background concentration (5.5 mg/kg) and the Unrestricted Use SCO (109 mg/kg) in both FP-B-16S (274 mg/kg) and FP-B-17S (369 mg/kg).

3.2 Temporary Piezometer Results

To assess groundwater quality beneath the footprint of the MOSF Tanks and to assess whether historic operations have impacted Site groundwater, 9 temporary piezometers were installed beneath the MOSF footprint. These 9 temporary piezometers include 5 piezometers (PZ A-1 through PZ A-5) beneath Complex A and 4 piezometers beneath Complex B (PZ B-1 through PZ B-4). Summary tables of the analytical data are included as Tables 13A and 13B. Figures 9A and 9B show analytical data with respect to the sample locations.

3.2.1 Complex A

Analytical results show that 7 VOCs and 7 SVOCs were detected in Site groundwater above applicable TOGS 1.1.1 GWQS or guidance values. Acetone, benzene, tetrachloroethene, toluene, ethylbenzene, styrene, and total xylenes were the VOCs detected above the GWQS or guidance values at Complex A. Toluene, ethylbenzene, and total xylenes were detected in concentrations that are four to five orders of magnitude above the GWQS and guidance values. These VOCs are typically not indicative of No. 6 fuel oil, especially at these concentrations. The origin of these compounds is likely associated with the FYN Paint and Lacquer VCP site, which is upgradient of Complex A.

Acetone was detected in three of the five samples with one concentration exceeding the guidance values. Acetone is also a contaminant of concern at the Fyn Paint site. The tetrachloroethene concentration is one order of magnitude above the groundwater standard but was reported as an estimated concentration due to the dilution factor associated with the toluene, ethylbenzene and total xylene concentrations. The source of tetrachloroethene, which was detected in only one sample, is not known.

Analytical data results also suggest that Site groundwater has been impacted by SVOCs. Total phenolic compounds (phenol, 2-methylphenol, 4-methylphenol, 2,4-dimethylphenol), benzo[a]anthracene, bis(2-ethylhexyl)phthalate, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, and indeno[1,2,3-cd]pyrene were detected at concentrations above applicable standards and guidance values. Concentrations ranged from 0.27 ug/l (benzo[a]pyrene in PZ A-4) to 75 ug/l (total phenolic compounds) in PZ A-1. Although these compounds are in exceedance of their respective TOGS 1.1.1 groundwater standard and guidance values, the compounds are not indicative of an impact associated with the MOSF tanks due to the absence of naphthalene. Naphthalene is a common indicator of fuel oils. The impacts associated with the polyaromatic hydrocarbons (PAHs) is likely more indicative of urban fill, whereas the phenolic compounds may be indicative of contaminants associated with the creosote piles or possibly

construction and building materials. However, creosote piles were not present at Complex A; thin walled, cast in place 60 ton concrete piles were present under this complex.

3.2.2 Complex B

To assess the groundwater quality beneath Complex B, four temporary piezometers were installed. Analytical results show that 4 VOCs and 12 SVOCs have been detected in Site ground water above applicable TOGS 1.1.1 GWQS or guidance values. VOCs detected above the GWQS/Guidance Values include benzene, toluene, ethylbenzene and total xylenes (BTEX). Although the BTEX compounds are often associated with gasoline, these compounds are also associated with creosote and Complex B contains numerous wood piles which were likely treated with creosote. These compounds are also associated with the upgradient Fyn Paint site, although the distance and cross gradient direction likely rule that property out as a source. Acetone and 2-butanone were also detected, but at concentrations below the TOGS guidance values. These compounds are also associated with the Fyn Paint site.

SVOCs detected in groundwater at Complex B include phenols (2-methylphenol, 4-methylphenol, 2,4-dimethylphenol), naphthalene, acenaphthene, fluorene, phenanthrene, benzo[a]anthracene, bis(2-ethylhexyl)phthalate, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, and indeno[1,2,3-cd]pyrene. The distribution of these compounds at Complex B is generally inconsistent. For example, total phenols were detected in concentrations exceeding the guidance values at PZ-B-1, PZ-B-2, and PZ-B-4 but not detected at PZ-B-3 whereas naphthalene exceeded the guidance values at PZ-B-2, PZ-B-3 and PZ-B-4, but not detected at PZ-B-1 and detected but at an estimated concentration in the PZ-B-1 duplicate sample. Acenaphthene was the only SVOC that exceeded the guidance value in each of the four groundwater samples.

With the exception of the SVOCs with low guidance values (0.002 ug/l), the exceeding concentrations were mostly on the same order of magnitude as the guidance values. However, the total phenols and naphthalene concentrations were two orders of magnitude above the guidance values. Considering the numerous and closely spaced piles at Complex B, the creosote piles are the likely source of those compounds.

4. CONCLUSIONS

The Site soil encountered during this investigation largely consists of urban fill. The analytical data for VOCs, SVOCs, pesticides, PCBs and metals are generally consistent with the chemical composition of urban fill or associated with creosote treated piles, which exist at Complex B. At Complex A, there appears to be two primary areas where elevated concentrations were detected.

One area is at the southeast corner of the complex, near the intersection of North First Street and River Street. A second area is near the East River, at the northwest corner of Complex A.

Near the southeast corner of the Site, VOCs have been impacted this area by contaminants that appear to be migrating from the Fyn Paint facility. Concentrations of ethylbenzene, toluene and total xylenes are in the double to triple digit part per million (ppm) range in the subsurface sample (FP A-3) collected at the water table in this area. Based on the results of soil samples collected from the surrounding borings (FP A-2, FP A-4, and FP A-5), the impacted area does not appear to extend far onto the Site. However, the groundwater sample collected at PZ A-4, which corresponds with soil sample location FP A-2, shows ethylbenzene and total xylene concentrations that are three and four orders of magnitude above the TOGS 1.1.1 GWQS. Therefore, the impacted groundwater apparently migrating from the Fyn Paint facility does not appear to be fully delineated to the northwest. Groundwater samples collected at PZ A-2 and PZ A-3, which were installed to the west of PZ A-1 have significantly lower concentrations of toluene, ethylbenzene and total xylenes.

Near the northwest corner of the Site, the area appears to be impacted by PAHs as evidenced by certain compounds exceeding the Unrestricted Use SCOs in subsurface soil samples and specifically those samples collected at FP A-16, FP A-21 and FP A-22. These samples are contiguous with respect to the sampling grid and may suggest a separate fill source from the rest of Complex A as no other sample location had PAH concentrations on this order of magnitude. Two other sample locations, FP A-17 and FP A-20, had SVOC exceedances of the Unrestricted Use SCOs (one and two exceedances, respectively). Therefore, the impacted fill appears to be horizontally delineated in this area.

For Complex B, the impacted area appears to be more widespread and less isolated considering 24 of the 40 samples collected have one or more SVOC concentrations that exceed the Unrestricted Use SCOs. Of these, 10 surface soil and 14 subsurface soil samples (24 total) have one or more SVOCs with concentrations that exceed the Unrestricted Use SCOs. Only 12 of the 40 surface and subsurface samples at Complex B have concentrations above the Manhattan background concentrations. These samples include seven surface samples and five subsurface samples.

However, with the exception of acetone at FP-B-3 S DUP (51 ug/kg) and FP-B-17 4.5' (97 ug/kg) and benzene, ethylbenzene and total xylenes at FP-B-11 3.5', no VOC concentrations exceeded the Unrestricted Use SCOs. Also, PCBs were not detected above the Unrestricted Use SCOs. Although a few metals were detected at concentrations exceeding the Unrestricted Use SCOs, only the zinc concentrations in FP-B-16 S and FP-B-17 S, the copper concentration in FP-B-16 S and the barium concentration in FP-B-17 S exceeded the Manhattan Background soil

concentrations. Considering the presence of PAHs and a lack of metals within Complex B, it is believed that the impacted soil is associated with the creosote piles as opposed to the urban fill that exists at this complex. Groundwater analytical data of samples collected from Complex B also supports this conclusion. Total phenols were detected in three of the four groundwater samples collected at Complex B, with concentrations exceeding the TOGS 1.1.1 GWQS. Phenols may be indicative of creosote related impacts.

Data collected during the perimeter investigation also suggests the presence of creosote treated wood as a potential source of Site contaminants. During the perimeter investigation, the SVOCs detected in the B9 sample were reported at higher concentrations in comparison to the remaining sampling locations. The boring log for B9 notes that the 6 to 10 foot interval (bgs) consisted mainly of wood. Boring B9 was near the southwest corner of Complex B and also had exceedances of Unrestricted Use SCOs for SVOCs. Based on historical Site use, it is possible that the wood may have been the remnants of a wooden support pile or railroad tie. The SVOC concentrations in the sample collected at B9 may be indicative of preserved wood and had impacted the sample collected from this boring.

In summary, the reported concentrations for the samples collected during this investigation do not appear to be indicative of any potential release from the MOSF. For the most part with some exceptions, the exceedances are within the same order of magnitude as Part 375 Unrestricted Use SCOs. Based on the analytical data, and meter readings and field observations during this investigation, there is no apparent indication of an impact to soil or groundwater caused by leakage from any of the tanks, ancillary piping, accidental discharges or other Site related activities.

However, it appears that contaminants of concern from the upgradient FYN property are evident at the southeastern side of Complex A, particularly noted by the toluene, ethylbenzene, and total xylenes concentrations detected in the soil and groundwater samples. The presence of these compounds, plus acetone in other samples, in the soil and groundwater suggests migration of impacted groundwater from an upgradient source is occurring. Migration of impacted groundwater is further supported by the historical groundwater sample results of wells installed along the east and south sides of Complex A, where toluene, ethylbenzene, xylenes and other paint manufacturing related chemicals have been detected. Based on the reported concentrations of these contaminants, the impact to groundwater at the Site from activities at the FYN property appears to be significant and continuing migration of the impacted groundwater is ongoing. The predominant migration pathway of these contaminants though the soils is via groundwater movement.

Notes:

**	Data was collected and supplied by LBG	STD[1]	Standard applies to sum of 1,2-, 1,3-, and 1,4-Xylene
STD	Groundwater Quality Standard	STD[2]	Standard is non-detect
GV	Groundwater Quality Guidance Value	ND	Compound not detected in sample

NA Not Analyzed - in later rounds of groundwater sampling a modified list of analytes was reported
NR Analysis of this compound was not requested by LBG
-- indicates no standard or guidance value provided in NYSDEC TOGS (1.1.1)
"< 5" Italicized numbers with preceding "<" indicate value is non-detect
45 Shaded values indicate exceedance of NYSDEC TOGS (1.1.1) Water Class GA standard or guidance value
A - Data compared to New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1) Ambient Water Quality Standards & Guidance Values & Groundwater Effluent Limitations

Data Source: Consolidated Edison

Notes:

**	Data was collected and supplied by LBG	STD[1]	Standard applies to sum of 1,2-, 1,3-, and 1,4-Xylene
STD	Groundwater Quality Standard	STD[2]	Standard is non-detect
GV	Groundwater Quality Guidance Value	ND	Compound not detected in sample
NA	Not Analyzed - in later rounds of groundwater sampling a modified list of analytes was reported		
NR	Analysis of this compound was not requested by LBG		
--	indicates no standard or guidance value provided in NYSDEC TOGS (1.1.1)		
"< 5"	Italicized numbers with preceding "<" indicate value is non-detect		
45	Shaded values indicate exceedance of NYSDEC TOGS (1.1.1) Water Class GA standard or guidance value		
A -	Data compared to New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1) Ambient Water Quality Standards & Guidance Values & Groundwater Effluent Limitations		

Data Source: Consolidated Edison

Table 6
GROUNDWATER ANALYTICAL RESULTS FOR MONITORING WELLS IMMEDIATELY ADJACENT TO MOSF
WESTERN PORTION OF NORTH FIRST STREET OIL STORAGE TERMINAL
87 and 105 RIVER STREET
BROOKLYN, NEW YORK

ND	Compound not detected in sample
NS	Well not sampled
NR	Not reported or not shown in LBG data tables
NA*	Analyte not analyzed
--	indicates no standard or guidance value provided in NYSDEC TOGS (1.1.1)
45	Shaded values indicate exceedance of NYSDEC TOGS (1.1.1) Water Class GA standard or guidance value
1 -	Data compared to New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1) Ambient Water Quality Standards & Guidance Values & Groundwater Effluent Limitations

Data Source: Leggette, Brashears, & Graham, Inc. (LBG) Quarterly Groundwater Monitoring Reports for Fyn Paint & Lacquer Co. Inc. 230 Kent Avenue, Borough of Brooklyn, City of New York VCP Site #V00380-2, VCP Index #W2-0873-00-10

Notes:

highlighted cells indicate exceedances of NYSDEC Part 375 SCOs

nd - compound was not detected at the MDL.

j - Indicates an estimated value.

b - The analyte was found in an associated blank, as well as in the sample.

p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit for VOCs

* - RPD of the LCS and LCSD exceeds the control limits for VOCs

* - LCS or LCSD exceeds the control limits for VOCs and SVOCs

NR - Analysis not Requested

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
NA - sample was not analyzed for these compounds
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit
* - RPD of the LCS and LCSD exceeds the control limits
* - LCS or LCSD exceeds the control limits
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:

highlighted cells indicate exceedances of NYSDEC Part 375 SCOs

nd - compound was not detected at the MDL.

j - Indicates an estimated value.

b - The analyte was found in an associated blank, as well as in the sample.

p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit for VOCs

* - RPD of the LCS and LCSD exceeds the control limits for VOCs

* - LCS or LCSD exceeds the control limits for VOCs and SVOCs

NR - Analysis not Requested

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

General Chemistry					
Percent Moisture - %	NS	20.9	13.6		26.4
Percent Solids - %	NS	79.1	86.4		73.6

Notes:

highlighted cells indicate exceedances of NYSDEC Part 375 SCOs

nd - compound was not detected at the MDL.

j - Indicates an estimated value.

b - The analyte was found in an associated blank, as well as in the sample.

p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit for VOCs

* - RPD of the LCS and LCSD exceeds the control limits for VOCs

* - LCS or LCSD exceeds the control limits for VOCs and SVOCs

NR - Analysis not Requested

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
NA - sample was not analyzed for these compounds
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit
* - RPD of the LCS and LCSD exceeds the control limits
* - LCS or LCSD exceeds the control limits
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:

Highlighted cells indicate exceedance of NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and Manhattan, New York background data.[1.]

Only analytical results that correspond with PAHs and Metals from RETEC Background Report displayed.

1. - RETEC Group, Inc. March 24, 2007. Characterization of Soil Background PAH and Metal Concentrations, Manhattan, New York.

ND - compound was not detected at the MDL.

NR - sample was not analyzed for these compounds

J - Indicates an estimated value.

B - The analyte was found in an associated blank, as well as in the sample.

P - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit

* - RPD of the LCS and LCSD exceeds the control limits

* - LCS or LCSD exceeds the control limits

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Notes:

Highlighted cells indicate exceedance of NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and Manhattan, New York background data.[1.]

Only analytical results that correspond with PAHs and Metals from RETEC Background Report displayed.

1. - RETEC Group, Inc. March 24, 2007. Characterization of Soil Background PAH and Metal Concentrations, Manhattan, New York. Table 4-3a. (PAHs) and Table 4-3b. (Metals)

ND - compound was not detected at the MDL.

NR - sample was not analyzed for these compounds

J - Indicates an estimated value.

B - The analyte was found in an associated blank, as well as in the sample.

P - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit

* - RPD of the LCS and LCSD exceeds the control limits

* - LCS or LCSD exceeds the control limits

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

1. INTRODUCTION

On behalf of Consolidated Edison Company of New York, Inc. (Con Edison), Henningson, Durham and Richardson Architecture and Engineering, P.C. (HDR) has performed a Site Investigation, Second Phase, to assess subsurface conditions of the former Major Oil Storage Facility (MOSF) at the North First Street Terminal (NFST) Site. The investigation was performed in accordance with the Site Investigation Work Plan – Second Phase, prepared by HDR and dated January 2012, which was approved by New York State Department of Environmental Conservation (NYSDEC) in a letter dated January 27, 2012 (Appendix A).

1.1 Site Overview

The NFST Site is located in Williamsburg, Brooklyn, Kings County, New York (Figure 1). The NFST Site exists in a predominately mixed residential and commercial community. Historically, the Site vicinity was predominantly manufacturing but in recent years, the manufacturing community has been displaced. Residences are now located to the north, across North Third Street. Commercial and light manufacturing properties remain east of the Site across River Street from the northern portion of the NFST MOSF. At the southern portion of the NFST MOSF, a closed paint factory is to the east. A New York Power Authority (NYPA) Gas Turbine Generation Station is to the south of NFST complex. The East River is to the west of the NFST MOSF.

The NFST Site also consists of an adjacent lot on the east side of River Street, between Metropolitan Avenue and North First Street. The address of this ancillary property (boiler/control house) is 214 Kent Avenue and it is bordered by Metropolitan Avenue to the north, FYN Paint and Lacquer Co. (FYN) to the south, and River Street to the west. The ancillary property occupies approximately 0.3 acres on modern Tax Block 2362, Lot 3. Newly developed residences are east of this lot, on the opposite side of Kent Avenue, replacing light manufacturing and commercial properties that existed up until approximately 2009.

The portion of the NFST facility that is the focus of this investigation is modern Tax Block 2355, Lot 1 and Tax Block 2361, Lot 1. These lots are to the west of the control house, across River Street. Both lots contained a complex of aboveground storage tanks (ASTs). Con Edison demolished the AST complex in 2011-2012. Based on the engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; these two complexes consisted of three tanks each with the following capacities:

- Complex A (southern tanks)
    - T-100 – 6,000,000 gallons

  - T-200 – 2,325,000 gallons
  - T-300 – 6,000,000 gallons
- Complex B (northern tanks)
  - T-400 – 6,000,000 gallons
  - T-500 – 6,000,000 gallons
  - T-600 – 4,950,000 gallons

Tank construction of the two complexes was different with respect to the supporting piles. Complex A, as detailed on engineering drawings, was constructed of steel reinforced concrete, 18 inch thick slab on top of 14 –inch thin walled, cast in place 60 ton concrete piles. Complex B was constructed 18 inches of steel reinforced concrete set on top of a mixture of 60 ton, 30 ton, and 25 ton creosote timber piles that ranged from 4 to 6 feet on center. Figure 2 shows the former Site layout including the MOSF ASTs and docks, and engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; detailing Complexes A and B are included as Appendix B

1.2 Regional Geology/Hydrogeology

The Site is in the Atlantic Coastal Plain physiographic province and is comprised of interbedded layers of sand, clay and marl. The marine deposits are Cretaceous and Quaternary in age. The drift deposits are derived from glacial activity that occurred during the Pleistocene Epoch. The total thickness of the marine and glacial deposits in Kings County ranges from 0 foot in northwest Brooklyn to 1,100 feet thick in northeastern Brooklyn.

The topography of the area slopes to the west toward East River. The elevation of the Site is approximately 11 to 15 feet above mean sea level (msl). The ground surface at the Site consists of poured concrete and asphalt pavement. The shallow sediments beneath the Site consist of a brown, medium to coarse grained sand with some silt and trace gravel. In general, the subsurface beneath the area consists of interbedded layers of sand, gravel, and clay and silt mixture to approximately 75 feet below ground surface (bgs). Bedrock beneath the Site is greater than 75 feet bgs. The regional direction of groundwater flow beneath the Site is to the west, toward the East River.

1.3 Site History and Previous Investigations

Holzmacher, McLendon & Murrell, P.C. (H2M) and HDR (formerly known as Lawler, Matusky and Skelly Engineering, LLC or also known as LMS) developed background information for the Site on behalf of Con Edison. The background information presented in *Phase I Environmental Site Assessment Report – Kings County Tax No. Block 2355, Lot 1, Block 2361, Lot 1, Block 2362, Lot 3 & Block 2376, Lot 6 – 214 Kent Avenue, Brooklyn, New York* prepared by H2M and

dated September 10, 1999 and *Phase II Site Investigation Report – North First Street Oil Storage Terminal* prepared by HDR and dated January 14, 2000, is summarized below.

A Phase I Environmental Site Assessment (ESA) was performed by H2M for the Con Edison NFST property and the former Pfizer property (no longer owned by Con Edison). Based on a review of available records, a number of Recognized Environmental Conditions (RECs) were identified. These RECs included the presence of above-ground storage tanks (ASTs) and underground storage tanks (USTs) and surface and subsurface soil conditions based on historic Site usage as well as the existence of toxic or hazardous material containers.

At the request of Con Edison, HDR performed a Phase II ESA, as documented in a report dated January 14, 2000. This Site investigation encompassed the NFST Site and the former Pfizer property located to the south of the NFST MOSF facility (between East River, River Street, Grand Street and North First Street). The Phase II investigation scope included:

- Investigation and sampling of a storm drain outside one of the onsite buildings and a manhole within another, both located on the former Pfizer property. Results from both of these sample locations indicate that six semi-volatile organic compounds (SVOCs) and eleven metals were detected above the NYSDEC Technical and Administrative Guidance (TAGM) Memo #4046 - Recommended Soil Cleanup Objectives (RSCOs), which were the regulatory criteria in effect at the time of the investigation.
- Thirteen soil borings were advanced into the water table at the former oil storage area and former Pfizer site. Select samples were collected and sent to a NYSDOH certified laboratory for volatile organic compound (VOC), semi-volatile organic compound (SVOC), metals, pesticides and polychlorinated biphenyls (PCBs) analyses. Laboratory results of the soil samples indicated VOC and SVOC concentrations above the NYSDEC RSCOs. Results for the metal analyses identified ten metals with concentrations above NYSDEC RSCOs. Based on the results, no other analytes were above applicable NYSDEC RSCOs.
- Groundwater samples were collected from four monitoring wells that were initially installed onsite (MW-1, MW-2, MW-3 and MW-4) as part of the MOSF permit. Only one (MW-4) of the four monitoring wells at the Site contained VOCs concentrations in groundwater that exceeded the NYSDEC Class GA standards. Seven metals were also detected above their respective GWQS while neither SVOCs nor polychlorinated biphenyls (PCBs) were detected in the four monitoring wells.

In addition to the above two documents, a 1996 Con Edison document reported that product containing VOCs was encountered in soil borings advanced for the cathodic protection

installation associated with the Con Edison 10,000-gallon UST located in the parking lot at 214 Kent Avenue, adjoining Con Edison's MOSF boiler/control house. The VOCs detected in the product sample included toluene, ethylbenzene and xylenes totaling 876,000 milligrams per liter (mg/l). NYSDEC Spill Number 96-04977 was assigned to the contamination identified adjacent to the UST. To confirm the 1996 report, additional borings were advanced in the vicinity of the UST by HDR in 1999 to characterize the subsurface conditions in this area. This investigation concluded that free phase product was encountered and toluene, ethylbenzene and xylene were detected at elevated concentrations.

In 2001, to assess subsurface soil near the Con Edison UST, Leggette, Brashears & Graham, Inc. (LBG) conducted a limited subsurface investigation associated with the adjacent Fyn Paint facility to the south. The limited subsurface investigation consisted of installing eight soil probes utilizing direct push drilling methods and four groundwater monitoring wells using the hollow stem auger (HSA) method. Of the eight probe borings advanced, four borings were located within the Con Edison property. Three borings were advanced in the NFST parking lot (CE-1, CE-2, and CE-3), and the fourth boring was advanced along the south side of the Complex B on Metropolitan Avenue (CE-4). The rest of the probe borings were advanced outside the Con Edison Property; one was located at the west end of Grant Street (GP-1), one was located on the north side of Complex B on North Third Street (GP-2), and two were located within the Fyn Paint building (GP-3 and GP-4). Laboratory results from this investigation indicate that soil and groundwater within the NFST parking lot was impacted by acetone, ethylbenzene, toluene, and xylene. Subsurface soil concentrations at the borings advanced at NFST ranged from non detect (CE-4) to 3,200,000 micrograms per kilogram (ug/kg) of xylene at CE-1 in subsurface soils. Analytical data from Site monitoring wells in this same vicinity confirmed that these VOCs have also impacted Site groundwater. Dissolved phase VOCs were detected at concentrations ranging from non detect (CE-4) to 1,400,000 ug/l (xylene in CE-2). This information is presented in LBG's *Subsurface Investigation and Remedial Action Plan*, dated August 2001 (LBG, 2001).

To better define the limited subsurface investigation, LBG conducted Supplemental Remedial Investigations in 2003, during which all boring and wells were placed in the public right of way. In 2005, LBG expanded their supplemental investigation by installing eight additional groundwater monitoring wells and two extraction wells. VOC concentrations in subsurface soil during this investigation ranged from 19,000 ug/kg at MW-22 (acetone) to 4,000,000 ug/kg of toluene (MW-22). Groundwater concentrations ranged from non detect in CE-4 to 66,000 ug/l of toluene (EW-1). Both MW-22 and EW-1 are within the NFST parking lot. This information is presented in LBG's *Supplemental Remedial Investigation Report*, dated September 2003 (LBG, 2003).

Fyn Paint has entered into a Voluntary Cleanup Agreement under the New York State Voluntary Cleanup Program (VCP). Under this VCP, LBG installed an Interim Remedial Measure (IRM) consisting of free phase product recovery and groundwater extraction system with effluent treatment. These activities are ongoing with the treatment system inside the Fyn Paint building and extraction points at the Kent Avenue parking lot area of the Con Edison Site. The IRM will be supplemented with a dual phase extraction (DPE) system as the remediation strategy to be implemented in 2012 following approval from NYSDEC. Currently, a quarterly groundwater gauging and sampling program of a monitoring well network (Figure 3) is being implemented to assess the impacts associated with the Fyn Paint facility.

In June 2011, HDR conducted a Site Investigation to assess subsurface conditions surrounding the MOSF tanks as part of the permanent closure of tanks and associated permits. As detailed in the *Site Investigation Report – Western Portion of North First Street Oil Storage Terminal, Block 2355, Lot 1 & Block 2361, Lot 1, 49 River Street, Brooklyn, NY* prepared by HDR (July 2011), soil borings were advanced along North Third Street, River Street, North First Street and both the north and south sides of Metropolitan Avenue. Results of this "Perimeter" investigation indicated 10 of the 18 samples collected exhibited some exceedances of Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and/or Protection of Groundwater SCOs. The chemical concentrations reported in the analytical report do not appear to be indicative of a No. 6 fuel oil release from the NFST MOSF. The exceedances, for the most part, are within the same order of magnitude as the Part 375 Unrestricted Use SCOs. However, contaminants of concern from the upgradient FYN property were evident in subsurface soil at the perimeter of Complex A, as evident from the acetone concentrations detected in the B12 and B17 soil samples. The Site Investigation Report also discussed groundwater sampling results of the Fyn Paint VCP monitoring program as well as the NFST MOSF monitoring program. Figure 3 shows the locations of the monitoring wells associated with both programs. Based on the groundwater sampling results of these wells, there does not appear to be a groundwater impact associated with the MOSF.

2. SITE INVESTIGATION ACTIVITIES

To supplement the June 2011 Perimeter Subsurface Investigation, HDR conducted an additional "Footprint" investigation to assess the soils directly under the concrete footprint of the MOSF Complexes A and B. As part of this "Footprint" investigation, a surface soil assessment as well as deeper subsurface soils assessment was completed after the demolition of the tank complexes. Based on a reduced sample frequency consistent with DER-10 Section 3.9(b)(2)iii(2) and Section 1.6(c), 42 sample locations were identified in the Site Investigation Work Plan Second

Phase. This sample frequency equates to one boring per 3,600 square feet, or an approximate 60 by 60 foot grid.

2.1 Field Mobilization/Utility Clearance

Prior to the mobilization of drilling equipment HDR contracted a private utility mark-out contractor, Diversified Geophysics of Mineola, New York, to mark out utilities and other underground anomalies within the work area. Other than piles to support the former tank complexes, no subsurface anomalies were identified during the geophysical survey. Therefore, a map showing the locations of the subsurface anomalies was not prepared.

Prior to implementing any intrusive activities, a utility clearance was conducted. The procedure entailed utility mark-outs utilizing the Code 753 process, obtaining and reviewing available utility drawings and a field reconnaissance to verify, to the extent possible, the location of utilities relative to the planned intrusive locations. Aquifer Drilling and Testing, Inc. (ADT) of Mineola, NY, the drilling firm selected for the probe drilling, called in the Code 753 request.

As an added precaution and part of the Con Edison intrusive investigation program, the upper 5 feet at each soil boring was excavated using non-mechanical methods to confirm the absence of utilities (soft dig). ADT was subcontracted to perform non-mechanical clearance at each borehole location. ADT utilized hand tools (posthole digger and digging bar), an air knife, or a combination of the two methods to excavate to five feet or groundwater, whichever was encountered first. During intrusive activities, HDR screened the headspace above the excavation with a Rae Systems MultiRae combination 4-gas monitor and photoionization detector (PID). The MultiRae combination meter has a PID to monitor for total VOC vapors as well as sensors to monitor for lower explosive limits (LEL), oxygen (O_2), carbon monoxide (CO), and hydrogen sulfide (H_2S). Elevated PID readings were detected at several borings including FP B-13, FP B-13 N 5', FP B-13 E 5', FP B-13 S5', FP B-13 S 10', FP B-13 W 5', FP B-13 W 10', FP A-8, and FP A-3 during the soft dig activities (refer to Figures 4A and 4B for boring locations). During intrusive subsurface drilling activities (temporary piezometer installation), elevated PID readings were detected at FP B-11/PZ B-2, FP B-20/PZ B-3, FP-B-13/PZ B-4, FP A-3/PZ A-1, FP A-4/PZ A-2, and FP A-2/PZ A-4. All other borehole locations had background levels as measured during the field activities.

Soils were classified during soft dig activities and recorded on boring logs (Appendix C). Typically, soils above the water table consisted of silty sands with varying amounts of brick, asphalt, concrete, gravel and cobbles. Upon completion of each borehole, each hole was backfilled with the cuttings removed from that location and the location was marked with orange

flagging for future documentation of the location using Differential Global Positioning System (DGPS).

2.2 Soil Borings

To assess the subsurface conditions within the footprint of the MOSF facility, 48 vertical soil borings were advanced (Figure 4A and 4B). The objective of these borings was to physically characterize subsurface soil conditions and allow for the collection of soil samples for laboratory analysis. In the footprint of Complex B, 20 borings were advanced (FP B-1 through FP B-20) as shown on Figure 4B, and 22 borings (FP A-1 through FP A-22) were advanced within Complex A (Figure 4A). Six additional delineation borings were also advanced within the footprint of Complex B to assess the elevated PID readings noted in soils from the FP B-13 borehole. No samples for laboratory analyses were collected from the six additional delineation borings.

ADT was subcontracted by HDR to advance the soil borings using direct push technology (DPT) drilling methods and tooling. However, due to a shallow water table, DPT was not utilized to collect soil samples but was used to install temporary piezometers. In most cases, the water table was encountered during hand clearing efforts, usually within three or four feet below ground surface (bgs). All borings were advanced to the water table.

A HDR environmental scientist was on-Site during the drilling activities to log soils and collect soil samples for laboratory analyses. Soils from each boring were described in accordance with the Unified Soil Classification System (USCS) and were field screened with the MultiRae combination meter to monitor subsurface soils and headspace of the boring holes. Samples were immediately screened with the MultiRae meter to identify areas where volatile organic vapors and/or methane may be present so that samples representative of a worst case situation could be collected for analyses. Observations and field screening data from each boring was recorded on boring logs, which are included in Appendix C. A summary of the PID readings of all borings is included as Tables 1A and 1B.

In addition to the PID screening, the boreholes were also screened with the other sensors as well. No readings above background LEL concentrations (0% LEL) were noted during the investigation except at FP A-3, where an LEL of 1% was measured during advancement of direct push tooling associated with the temporary piezometer installation. Oxygen, CO, and H_2S readings from the boreholes were the same as background conditions. The readings on the other sensors were the same as background conditions during the investigation activities.

Subsurface soils observed during the subsurface investigation were described as fine to medium sands with varying amounts of silts and debris such as brick, concrete coal, ash, wood and glass. Depths to groundwater ranged from 2.5 to 6 feet bgs.

2.2.1 Soil Sampling and Analyses

As part of this "Footprint" subsurface investigation, 84 soil samples were collected from 42 soil borings. At each boring, one sample was collected from the surface and the second sample from the interval that exhibited the highest PID reading. In the absence of an elevated PID reading, the second sample was collected from the interval immediately above the groundwater table. Upon collection, samples were transferred directly into laboratory-supplied glassware. The portion of the sample collected for VOCs was transferred to the sample containers first followed by the other parameters, as needed. Each container was then labeled with the appropriate sample identification number and sample depth, the analytical parameters to be analyzed, the date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Soil samples submitted to the laboratory were analyzed for VOCs using EPA Method 8260B and SVOCs using EPA Method 8270C (base-neutral compounds only). In addition, samples from selected locations were analyzed for Target Analyte List (TAL) metals via EPA Method 6010B, pesticides following EPA Method 8081, PCBs using EPA Method 8082, and modified total petroleum hydrocarbons (TPH) following a modified EPA Method 8015. These locations were selected to provide a representation of conditions across the Site or at a borehole location that exhibited elevated PID reading and/or showed signs of contamination (odors, soil staining or sheen). Tables 2A and 2B provide the soil sample analytical summary.

Upon completion of each borehole, sampling equipment (e.g., Macrocore® sampler) was decontaminated with an Alconox and tap water wash, followed by a de-ionized or distilled water rinse. Drill cuttings that were observed to be impacted were placed in a Department of Transportation (DOT) specified drum for subsequent waste characterization sampling and off Site disposal. Soil from one borehole (FP B-13) showed some evidence of a potential impact with a heavy sheen noted on the soils. Soils from this borehole were drummed, with an estimated volume of approximately 1/3 full. One other borehole (FP A-3) showed signs of being potentially impacted. However, no excess soil from other locations was generated. At borehole locations where no evidence of a potential impact was observed, cuttings were returned to the subsurface at the location that the cuttings were generated.

The location of each boring was surveyed using a DGPS for documentation purposes. Due to the proximity of the borings to adjacent buildings/structures, there was potential that satellite signals could be disrupted, which could distort the plotted location. Therefore, on boreholes where poor satellite distribution was noted, the borehole was triangulated using two fixed points such as fire

hydrants or manholes in addition to using a DGPS. The DGPS data and triangulations were used to prepare a figure that most accurately locates each boring (Figures 4A and 4B).

2.3 Temporary Piezometer Installations

ADT was subcontracted by HDR to advance soil borings and install temporary piezometers at select locations within the footprint of the MOSF tanks. These temporary piezometers were installed using DPT drilling methods and tooling. All borings were advanced continuously in five-foot increments using a 2-inch diameter Macrocore® barrel with dedicated PVC liners. Each borehole was advanced into the water table. HDR installed 9 temporary piezometers within the footprint of the former tank complexes to assess the groundwater conditions beneath the tank farm (Figures 5A and 5B). Each piezometer was offset slightly from the boring location to avoid collecting an excessively turbid groundwater sample which could bias the analytical results. Five piezometers were installed in Complex A and 4 piezometers were installed in Complex B. An HDR environmental scientist was on-Site during the drilling activities to observe the installation process and to log the boreholes. Consistent with the soil borings, subsurface soils observed during the temporary piezometer installations were described in accordance with the Unified Soil Classification System (USCS). Soils collected from borehole advancement were also field screened with a MultiRae meter to monitor subsurface conditions. Observations and field screening data from each boring was recorded on boring logs, which are included in Appendix D.

Upon reaching the termination depth for each borehole, a 10 foot length of 1 inch diameter polyvinyl chloride (PVC), 0.002 inch slot screen was placed in the borehole such that the screened section of each piezometer intersects the water table. Piezometer construction logs documenting the construction details are included as Appendix E and a summary of temporary piezometer construction details is provided on Table 3. Following installation of the temporary piezometers, the groundwater was allowed to equilibrate to near steady state conditions. Once steady state conditions were obtained, the groundwater within the piezometer was gauged with an oil water interface probe to the nearest one-hundredth of a foot to provide a depth to water (DTW) measurement and/or a depth to product (DTP) measurement, if free phase product was encountered. Measurements were recorded from the surrounding ground surface and are included in Appendix F. Groundwater depths ranged from 2.25 feet bgs to 5.85 feet bgs. No measurable free product was encountered in any of the piezometers during this investigation.

2.3.1 Groundwater Sampling and Analyses

As part of this "Footprint" subsurface investigation, one groundwater sample was collected from each of the 9 temporary piezometers; five samples from Complex A and four samples from Complex B.

Upon completion of groundwater gauging, dedicated ¼ inch, inside diameter (ID) low density polyethylene (LDPE) tubing was placed into each temporary piezometer and connected to a variable speed peristaltic pump utilizing laboratory-grade silicone tubing. The piezometers were then purged of approximately 0.33 ounces to 3 gallons (gal) of water in an effort to collect turbid free samples. Purged water was collected in a five gallon pail and was assessed using olfactory senses for impacts for subsequent disposal.

Once turbid free conditions were reached, groundwater samples were collected directly into laboratory supplied glassware. Each container was then labeled with the appropriate sample identification number, parameters to be analyzed, date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Purge water was determined to be free of visible contamination (free phase product or heavy sheen) and was then discharged back into the borehole from which it was purged following sample collection.

All groundwater samples were analyzed for VOCs using EPA Method 8260B, SVOCs using EPA Method 8270C (base-neutral compounds only). Also, a sample from PZ A-1 (FP A-3) was analyzed for PCBs using EPA Method 8082 and modified Total Petroleum Hydrocarbon (TPH) following a modified EPA Method 8015, based on the presence of a heavy sheen and elevated PID readings that were noted during borehole advancement.

2.4 Review of MOSF and FYN VCP Groundwater Monitoring Data

In addition to the subsurface soil and groundwater evaluation, six years of MOSF compliance sampling data and three years of Fyn Paint and Lacquer Company, Co. groundwater remediation data were also evaluated as part of this Investigation. This information was previously summarized in the June 2011 Site Investigation Report, but is updated herein considering the groundwater data collected since that investigation. Monitoring well locations associated with the Con Edison MOSF and the Fyn Paint VCP are shown on Figure 3. A summary of the monitoring well construction details is provided on Table 4. A discussion of the analytical results is provided below.

2.4.1 North 1st Street Major Oil Storage Facility Data (MOSF)

As part of the MOSF annual sampling program, four monitoring wells located in proximity to the tank farm were gauged on a monthly basis and sampled on an annual basis. These wells are identified as NTMW-1, NTMW-2, NTMW-3, and NTMW-4, (also referred to as MW-1 through MW-4). Under the MOSF requirements, the samples from these wells were analyzed for SVOCs only, but due to the litigation associated with the Fyn Paint facility, VOCs were subsequently added. Data dating back approximately to 2001 shows that the samples were regularly analyzed for VOCs and SVOCs using EPA Methods SW8260B and SW8270C with some analytes being analyzed using EPA 624/8260B and EPA 625/8270C. In 2007, SVOCs were analyzed using EPA Method SW8270B. Only selected analytes were reported in 2011 using EPA Method SW8021 for VOCs and EPA Method SW8270C for SVOCs. The groundwater samples collected in March 2012 were not submitted for SVOC analyses. Groundwater analytical data for NFST MOSF wells is provided on Table 5.

NTMW-1, installed as a stick-up protective casing well at the west end of Metropolitan Avenue between the two tank farms, had detections of acenaphthene (0.48 ug/l) and anthracene (0.03 ug/l) during the March of 2011 sampling event. However, no other compounds were detected in the 2010 or 2011 sampling events. Although these two compounds were detected at well NTMW-1, the concentrations are well below the most restrictive guidance value in the Division of Water Technical and Operational Guidance Series (1.1.1) (TOGS 1.1.1) of 5.3 ug/l (TOGS Class A waters) for acenaphthene and 3.3 ug/l (TOGS Class A waters) for anthracene. Similarly, toluene (2.2 ug/l) was detected in NTMW-1 in March 2012, but this concentration is below the groundwater quality standard of 5 ug/l.

MOSF Well NTMW-2 was installed with a stick-up protective casing at the west end of North First Street. Within the last two years (2010 and 2011), no VOCs or SVOCs were detected at concentrations above their associated detection limits at MOSF Well NTMW-2. No VOCs were detected in the sample collected from NTMW-2 in March 2012.

MOSF well NTMW-3 was installed with flush mount surface completion near the west end of North Third Street. Analyses of a sample collected from NTMW-3 showed no compounds were detected in the March 2010 sampling event. However, in March of 2011, several SVOCs were detected. These compounds are summarized in Table 5. NTMW-3 is located between the oil storage facility and a new apartment building, in a publicly accessible area. Due to the street cleaning, snow clearing and potentially public access, the well had been compromised. Construction associated with the redevelopment of North 3rd Street and the new apartment building has further damaged the monitoring well. The well was subsequently closed in accordance with New York State Department of Environmental Conservation procedures in

November 2011 due to its being compromised. These detections are possibly the result of stormwater runoff entering the compromised well.

NTMW-4 was installed as a flush mount well within the sidewalk along the west side of River Street between Metropolitan Avenue and North First Street. It is the closest MOSF monitoring well to the Fyn Paint and Lacquer building. Several VOCs have been detected in the samples collected from this monitoring well over the past two years. No SVOCs were detected above detection limits in either the March 2010 or March 2011 sampling events. In March 2012, three chlorinated VOCs (chlorobenzene at 5.9 ug/l, cis-1,2-dichloroethene at 3.4 ug/l, and 1,1-dichloroethane at 3.9 ug/l) were detected in this well. However, only the chlorobenzene concentration was above the groundwater quality standard.

2.4.2 Fyn Paint and Lacquer Site

The Fyn Paint VCP groundwater monitoring program currently consists of quarterly sampling of up to 30 wells and piezometers for VOCs. However, several wells were subsequently removed or reduced to annual sampling from the Fyn Paint monitoring program due their distance from the Fyn Paint contamination source. Because of the proximity of these Fyn Paint wells to the MOSF, the data set was reviewed to assess groundwater conditions within the NFST MOSF vicinity. Of the wells monitored as part of the Fyn Paint VCP, nine wells are immediately adjacent to the NFST MOSF. In addition to the four Con Edison MOSF wells (NTMW-1 through NTMW-4), these nine wells also include MW-10, MW-12, MW-14, GP-2, and CE-4. Although quarterly groundwater samples collected as part of the Fyn Paint VCP investigation date back to February 2008 and seven sporadic groundwater sampling events occurred from September 2001 through March 2007, only the data collected from the first quarter 2009 through first quarter 2012 are summarized herein. Groundwater analytical data for Fyn Paint VCP wells adjacent to the MOSF wells is provided on Table 6 and a summary of all Fyn Paint VCP wells is included as Appendix G.

Over the past three years, approximately 275 groundwater samples were collected for the Fyn Paint VCP, excluding quality control samples, and analyzed for VOCs following EPA Method 8260. VOCs are the primary contaminants of concern associated with the Fyn Paint site and several VOCs were detected at concentrations in excess of TOGS 1.1.1 Groundwater Quality Standards (GWQS). The predominant Fyn Paint contaminants of concern - acetone, benzene, toluene, ethylbenzene, and total xylenes - were detected most frequently and at the highest concentrations of the VOCs.

Acetone was detected at levels above the GWQS of 5 ug/l in eight Fyn Paint VCP wells: ASW-1 (sampled one time only), EW-1, MW-15, MW-16, MW-21, MW-22, MW-24, and MW-28.

None of these wells are adjacent to the NFST MOSF. Concentrations ranged from 11 ug/l in the MW-24 sample (2nd quarter 2011) to 800,000 ug/l in the MW-28 sample (2nd quarter 2010). In general, concentrations have fluctuated from event to event with the lowest average concentrations being detected in November 2009. According to the LBG report, the decrease noted between June 2010 and September 2010 can be attributed to the start-up of the groundwater pump and treat system at the end of August 2010. However, the variation in concentrations may also be attributed to other factors such as seasonal fluctuations, sampling methods, or hydrogeologic factors. Acetone is not a constituent of fuel oil. It is known to have been used at the Fyn Paint facility.

In both the MOSF and Fyn Paint VCP wells, benzene concentrations in the groundwater samples range from 1.3 ug/l reported in February 2009 at MW-8 to 360 ug/l reported in September 2010 at MW-13. Benzene was also detected in 11 additional wells over the course of the thirteen sampling events: EW-1, GP-1, MW-4, MW-6, MW-9A, MW-10, MW-15, MW-16, MW-21, MW-24, and MW-28, each of which is associated with the Fyn Paint VCP. With the exception of MW-10, these wells are either cross gradient or upgradient of the MOSF. The benzene concentration detected in MW-10 was 2.2 ug/l, during the second quarter of 2010. Benzene was not detected in this well during the 12 other quarters in this three year period. Based on the distribution of the benzene concentrations, the source of the benzene is likely an off-Site source or sources.

For the Fyn Paint VCP investigation, toluene concentrations ranged from 2.6 ug/l at MW-8 in June 2010 to 430,000 ug/l at MW-13 in March the 3rd quarter of 2011. Toluene was detected in 155 samples with 151 sample concentrations exceeding the GWQS of 5 ug/l. A general comparison of the concentration detected during the sampling events indicates a slight increase of toluene in the groundwater quality samples over this timeframe. Of the wells immediately adjacent to the MOSF, toluene was most frequently detected in the sample collected from MW-12 with the highest concentration (13,000 ug/l) detected in May 2009. Over the past three years, the samples collected from MW-4 in February 2010 (30 ug/l), from MW-10 in June 2010 (1,100 ug/l) from MW-14 in December 2011 (29 ug/l), MW-20 in September 2010 (30 ug/l), and from CE-4 in December 2009 (42 ug/l) were the only other wells immediately adjacent to the MOSF that showed detections for this compound. Considering the toluene distribution, the MOSF does not appear to be a source of this compound.

For the Fyn Paint VCP investigation, the concentrations of ethylbenzene range from 2.1 ug/l as reported at MW-10 in December 2010 to 34,000 ug/l at MW-22 in September 2011. Of the 147 samples where ethylbenzene was detected, 135 concentrations exceeded the GWQS of 5 ug/l. Of the wells immediately adjacent to the MOSF, ethylbenzene was most frequently detected in

MW-12, with the highest concentrations (15,000 ug/l in May 2009 and March 2010). Ethylbenzene was also detected in 4 other wells, MW-4 (high of 150 ug/l, March 2010), MW-10 (high of 1,100 ug/l, June 2010), MW-20 (high of 19 ug/l, September 2010) and CE-4 (detected only once in March 2011 at 16 ug/l).

The overall concentrations of total xylenes have been decreasing on average over the last two years though the number of detects per sampling event have risen indicating that the concentration of xylenes in the groundwater is becoming more dispersed over time. Total xylenes have been detected above the GWQS of 5 ug/l in 176 of the 275 samples collected. A maximum concentration of 144,000 ug/l was detected at MW-22 in September of 2011 and the lowest detected concentration of 2.1 was recorded at MW-27 in March of 2011.

Eleven other compounds were also detected at concentrations exceeding the GWQS in wells adjacent to the MOSF include 2-butanone, chlorobenzene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,1-dichloroethane, 1,2-dichlorobenzene, isopropylbenzene, 1,2,3-trichloropropane, trichloroethene, vinyl chloride, and tetrahydrofuran. None of these compounds are associated with fuel oil. The source of these compounds is unclear although documentation exists regarding Fyn Paint's use of 2-butanone.

Naphthalene, a common constituent of fuel oils, was not detected in any of the groundwater samples collected over this three year period.

2.5 Review of Soil Gas Sampling Data

In addition to groundwater results, historic soil vapor data associated with the Fyn Paint VCP were also evaluated. As part of the Fyn Paint VCP, the nearest soil gas point to the MOSF was installed at the northwest corner of North First Street and River Street. Based on the results of a soil gas sample collected from that point indicated 1,1,1-trichloroethane (TCA) was present in the soil vapor at a concentration of 680 micrograms per cubic meter ($\mu g/m^3$), as presented in LBG's *Soil Vapor Intrusion Investigation Work Plan* (LBG, 2007). Under the New York State Department of Health Guidance for Vapor Intrusion, TCA concentrations in sub-slab samples are actionable for monitoring or mitigation at 100 $\mu g/m^3$. TCA is not a component of No. 6 fuel oil, but is a solvent used in inks, paints, adhesives and other coatings.

3. ANALYTICAL RESULTS DISCUSSION

3.1 Soil Boring Results

The analytical results of the samples collected during the 2012 "Footprint" Investigation were compared to NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and

Protection of Groundwater SCOs. Based on the laboratory analytical results of the 84 samples (42 surface, and 42 subsurface samples), the soils across the Site generally appear consistent. However, exceedances of some of the above SCOs are reported. A summary of the number of samples with one or more SCO exceedances is presented in the following table (Manhattan Background concentrations for SVOCs and metals are also listed for comparative purposes).

Sample Parameter	No. of Samples Collected	Unrestricted Use SCO	Protection of Groundwater SCO	Manhattan Background
VOCs	84	11	11	NA
SVOCs	84	35	30	15
Pesticides	17	7	0	NA
PCBs	17	3	0	NA
Metals	17	17	4	3

Figures 6A, 6B, 7A, 7B, and 8A, 8B show the locations with exceedances of the Unrestricted Use, and Protection of Groundwater SCOs as well as compared to Manhattan Background soil concentrations (The RETEC Group, 2007) for Complex A and Complex B. A summary of the surface soil analytical results with comparison to the Unrestricted land use SCOs is presented in Tables 7A and 7B. Tables 8A and 8B provides a summary of the subsurface analytical results in comparison to the Unrestricted land use SCOs. A summary of surface soil analytical results in comparison to Protection of Groundwater SCOs is presented in Tables 9A and 9B. Tables 10A and 10B provide a summary of subsurface soil analytical results in comparison to Protection of Groundwater SCOs. Tables 11A and 11B provide a summary of surface soil analytical results in comparison to Manhattan Background, and Tables 12A and 12B provide a summary of subsurface soil analytical results in comparison to Manhattan Background concentrations. The complete analytical data packages are included as Appendix H.

3.1.1 Complex A

As part of this investigation, 22 borings were advanced within the "Footprint" of the MOSF at Complex A. One surface sample (22 total samples) and one subsurface sample (also 22 total samples) were collected from each location. Samples were analyzed at a NYSDOH certified lab for VOCs and SVOCs. From select locations, samples for pesticides, PCBs, and TAL metals analyses were also collected. If elevated PID readings or visual signs of contamination were noted, a modified TPH analysis was also requested. Analytical results were compared to Unrestricted Use SCO, Protection of Groundwater SCOs, and Manhattan Background

concentrations. A summary of the analytical results are included as Table 7A, 8A, 9A, 10A, 11A, and 12A, and a graphic summary is included as Figure 6A, 7A, and 8A.

Eleven out of the 22 surface samples collected have concentrations above Part 375 Unrestricted Use SCOs. Six samples contained VOC exceedances, four samples contained SVOC exceedances, five samples contained metal exceedances, one sample exceeded for pesticides and one sample exceeded for PCBs.

Acetone was the only VOC detected at concentrations greater than the Unrestricted Use SCO of 50 ug/kg. Analytical results of acetone ranged from 51 ug/kg to 220 ug/kg. No other VOC compounds were detected at concentration in excess of their respective SCO.

Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene were the only SVOCs detected at concentrations above their respective Unrestricted Use SCOs. In the surface samples, concentrations of these PAH compounds ranged from 620 ug/kg (indeno(1,2,3-cd)pyrene) in borehole FP A-17 SUR to 1,800 ug/kg (benzo(b)fluoranthene) in FP A-4 SUR.

Concentrations of five metal compounds (chromium, copper, lead, zinc, and mercury) exceed their respective Unrestricted Use SCOs in the surface samples. Chromium was detected in all five samples where Unrestricted Use SCOs were exceeded. Concentration of chromium ranged from 10.4 ug/kg (FP A-21 SUR) to 26.8 ug/kg in samples FP A-4 SUR. Lead and zinc were detected in 3 samples (FP A-1 SUR, FP A-4 SUR and FP A-15 SUR) at concentrations above the Unrestricted Use SCOs. Lead concentrations ranged from 106 mg/kg in FP A-1 SUR to 181 mg/kg in FP A-15 SUR above the Unrestricted Use SCO of 63 mg/kg. Zinc concentrations ranged from 131 to 179 mg/kg, above the Unrestricted Use SCO of 109 mg/kg. Copper and mercury were detected above the Unrestricted Use SCO in 2 samples each. Copper was detected above the Unrestricted Use SCO of 50 mg/kg in samples collected from FP A-1 SUR (62.2 mg/kg) and FP A-15 SUR (67.9 mg/kg). Both exceedances are on the same order of magnitude as the SCO. Mercury was also detected in 2 samples collected (FP A-15 SUR and FP A-21 SUR). Concentrations ranged from 0.29 mg/kg to 0.98 mg/kg, above the Unrestricted Use SCO of 0.18 mg/kg.

Pesticides and PCBs were also detected above Unrestricted Use SCO in one sample (FP A-4SUR). Pesticide concentrations were on the same or one order of magnitude above the respective SCO. Concentrations of 4,4'-DDD, 4,4'-DDT and dieldrin were detected above the Unrestricted Use SCOs of 3 ug/kg, 3 ug/kg, and 5 ug/kg respectively. Concentrations ranged from 7.1 ug/kg (dieldrin) to 19 ug/kg (4,4'-DDT). Aroclor 1254 was the only PCB that was detected. The Aroclor 1254 concentration detected was 220 ug/kg, which is above the Unrestricted Use SCO of 100 ug/kg (for total PCBs).

At Complex A, the surface sample that appears to be most impacted was collected at FP-A-4, where VOCs, SVOCs, pesticides, PCBs and metals concentrations all exceeded the Unrestricted Use SCOs.

Results of the subsurface samples show exceedances of the Unrestricted Use SCOs at nine locations: FP-A-3, FP-A-8, FP-A-13, FP-A-15, FP-A-16, FP-A-17, FP-A-20, FP-A-21, and FP-A-22. VOCs exceeded the Unrestricted Use SCO at FP-A-3 and FP-A-15. At FP-A-3, concentrations of ethylbenzene, toluene and total xylenes were above the Unrestricted Use SCOs of 1,000 ug/kg, 700 ug/kg, and 260 ug/kg, respectively. At FP-A-15, the acetone concentration (55 ug/kg) exceeded the Unrestricted Use SCO of 50 ug/kg.

In the subsurface samples, five of twenty-two samples were reported to have SVOC concentrations exceeding the Unrestricted Use SCOs. The SVOCs with concentrations exceeding the Unrestricted Use SCOs are PAHs, specifically benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene. In general, the concentrations of these compounds were an order of magnitude above the Unrestricted Use SCOs. However, not all compounds exceeded the Unrestricted Use SCOs in each of the five samples. The sample collected from FP-A-16 appears to have the highest SVOC concentrations detected.

Metal concentrations exceeded the Unrestricted Use SCOs in each of the four subsurface samples collected for metal analyses. Chromium concentrations exceeded the SCO in each sample whereas lead and mercury concentrations exceeded the SCO in two of the four samples (FP-A13 and FP-A-21). Barium, copper, and nickel exceeded the Unrestricted Use SCO in one sample only, FP-A-21. With the exception of nickel, each exceeding concentration at FP-A-21 was an order of magnitude above the cleanup objective.

PCBs and pesticides were detected at concentrations exceeding the Unrestricted Use SCOs in two of the four subsurface samples collected for these analyses (FP-A-13 and FP-A-21). At FP-A-13, 4,4'-DDT (5.9 ug/kg) and Aroclor 1254 (110 ug/kg) were detected above the Unrestricted Use SCOs of 3 ug/kg and 100 ug/kg, respectively. At FP-A-21, three pesticides, 4,4'-DDD (11 ug/kg) 4,4'-DDE (6.9 ug/kg) and 4,4'-DDT (13 ug/kg) had concentrations exceeding the Unrestricted Use SCO of 3 ug/kg for each pesticide. Concentrations of Aroclors 1254 (62 ug/kg) and 1260 (61 ug/kg) in the FP-A-21 subsurface sample were below the Unrestricted Use SCO, but the total PCB concentration of 123 ug/kg was above the 100 ug/kg cleanup objective.

With respect to the Protection of Groundwater SCOs, one VOC, three SVOCs, and one metal were reported to have concentrations that exceed the guidance in surface soil samples. Acetone

exceeded the Protection of Groundwater SCO (50 ug/kg) in six samples with the high concentration of 220 ug/kg in sample FP A-11 SUR. The other acetone Protection of Groundwater SCO exceedances were slightly over the SCO with concentrations ranging from 51 ug/kg to 63 ug/kg, on the same order of magnitude as the SCO. The three SVOCs that exceeded the Protection of Groundwater SCOs in the surface samples were benzo(a)anthracene and chrysene, both in three samples (FP A-4 SUR, FP A-7 SUR, and FP A-13 SUR) and benzo(b)fluoranthene in one sample (FP A-4 SUR). Chromium is the only metal with Protection of Groundwater SCO exceedances, occurring in two samples, FP A-1 SUR and FP A-4 SUR, with concentrations of 21.4 ug/kg and 26.8 ug/kg, respectively.

For the subsurface samples, the Protection of Groundwater SCOs were exceeded for VOCs, SVOCs, and metals. Samples with VOC exceedances include FP-A-3 (4.0-4.5) where ethylbenzene, toluene and total xylenes exceeded the criteria and FP-A-15 (4.0-4.5) where acetone exceeded the criteria. The samples with SVOC Protection of Groundwater exceedances include FP-A-16 (3.5-4.0), FP-A-21 (4.5-5.0) and FP-A-22 (3.5-4.0). The specific SVOCs that exceeded the criteria include benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene. Metals that exceeded the Protection of Groundwater SCOs include chromium in FP A-8 (4.0-4.5), and barium, chromium, lead and mercury in FP-A-21 (4.5-5.0).

The SVOC and metal analytical results were also compared to background PAH and metal concentrations in Manhattan soils in combination with the Unrestricted Use SCOs. At Complex A, there were no exceedances of both combined criteria in any of the surface soil samples. For the subsurface samples, three locations, FP-A 16 (3.5-4.0), FP A-21 (4.5-5.0), and FP A-22 (3.5-4.0), each had 7 PAHs with concentrations that exceeded both criteria. Only one subsurface sample, FP A-21 (4.5-5.0), had metals with concentrations exceeding both criteria. These metals include barium, chromium, copper, and nickel.

3.1.2 Complex B

As part of this investigation, 20 borings were advanced within the “Footprint” of the MOSF at Complex B. One surface sample (20 total samples) and one subsurface sample (also 20 total samples) were collected from each location. Samples were analyzed at a NYSDOH certified lab for VOCs and SVOCs. From select locations, samples for pesticides, PCBs, and TAL metals analyses were also collected. If elevated PID readings or visual signs of contamination were noted, a modified TPH analysis was also requested. Analytical results were compared to Unrestricted Use SCO, Protection of Groundwater SCOs, and Manhattan Background soil concentrations. Summaries of the analytical results for the surface and subsurface samples are

included as Table 7B, 8B, 9B, 10B, 11B, and 12B, and graphic summaries are included as Figure 6B, 7B, and 8B.

VOC analytical results show only one compound (acetone) with a reported concentration above the Unrestricted Use SCOs in surface soils. The acetone concentration was 51 ug/kg, above the SCO of 50 ug/kg. No other VOCs were detected in surface soil samples at concentrations exceeding the Unrestricted Use SCOs. Of the subsurface samples, only two locations, FP-B-11 3.5' and FP-B 17 4.5', had exceedances of the Unrestricted Use SCOs. In the FP-B-11 3.5' sample, concentrations of benzene (180 ug/kg), ethylbenzene (1,300 ug/kg) and total xylenes (1,600 ug/kg) exceeded the SCOs of 60 ug/kg, 100 ug/kg, and 260 ug/kg, respectively. At FP-B-17 4.5', the acetone concentration (97 ug/kg) was above the Unrestricted Use SCO of 50 ug/kg. However, this concentration was flagged with a "B", indicating it was also detected in the method blank associated with that sample.

At Complex B, concentrations of several SVOCs exceeded the Unrestricted Use SCOs. Of the 20 surface soil samples, 11 samples had one or more SVOC with concentrations exceeding the Unrestricted Use SCOs. These compounds included up to 8 PAHs, specifically benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzofuran, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene, that exceeded the Unrestricted Use SCOs. Of these compounds, benzo(b)fluoranthene and chrysene had the most exceedances (10) in the surface samples. The surface soil samples with the highest concentrations appear to be FP-B-2 S and FP-B-7 S.

For the subsurface soil samples, 15 of the 20 samples collected had SVOC exceedances above the Unrestricted Use SCOs. These individual SVOCs are the same compounds listed above for the surface soil samples. In general, the detected concentrations were on the same or one order of magnitude above the Unrestricted Use SCOs. The subsurface sample with the highest concentrations is FP-B-11 3.5', where the concentrations were generally an order of magnitude above the cleanup objectives. This subsurface sample is the only location where naphthalene was detected at a concentration exceeding the Unrestricted Use SCO. The naphthalene concentration at this location was reported at 13,000 ug/kg, above the cleanup objective of 12,000 ug/kg.

Pesticides were detected in four samples at concentrations exceeding the Unrestricted Use SCOs. These samples include two surface samples, FP-B-16 S and FP-B-17 S, and two subsurface samples, FP-B-2 3' and FP-B-20 4.5'. The specific pesticides that exceeded the Unrestricted Use SCOs include 4,4'-DDD, 4,4'-DDE, and 4,4'-DDT. The exceedances were generally on the same or one order of magnitude above the SCOs.

PCB concentrations did not exceed the Unrestricted Use SCOs in any sample collected from Complex B during this investigation. The highest detected concentration was 72 ug/kg of Aroclor 1254 in sample FP-B-20 4.5'.

Metal concentrations exceeded the Unrestricted Use SCOs in 8 surface and subsurface soil samples at Complex B. The specific metals include barium, chromium, copper, lead, mercury, and zinc. With the exception of lead and copper, the exceedances were on the same order of magnitude as the cleanup objectives. The highest detected lead concentration was 274 mg/kg in sample FP-B-17 S, above the Unrestricted Use SCO of 63 mg/kg. The highest detected copper concentration was 154 mg/kg in sample FP-B-16 S, above the cleanup objective of 50 mg/kg. No other metal concentrations exceeded the Unrestricted Use SCOs at Complex B.

Protection of Groundwater SCOs were exceeded for VOCs in three samples at Complex B. The specific VOCs include acetone in the duplicate sample of FP-B-3 S and FP-B-17 4.5' and both benzene and ethylbenzene in FP-B-11 3.5'. With the exception of the benzene concentration, the exceedances were on the same order of magnitude as the SCO. The benzene concentration was one order of magnitude above the SCO.

Five individual SVOCs were reported with concentrations exceeding the Protection of Groundwater SCOs in the surface and subsurface samples. These compounds include benzo(a)anthracene (in 22 samples), benzo(b)fluoranthene (in 12 samples), benzo(k)fluoranthene (in 3 samples), chrysene (in 24 samples), and naphthalene (in one sample). In general, the exceedances were on the same order of magnitude as the SCO. The most impacted boring with respect to this criteria is FP-B-11 3.5', where the exceedances were an order of magnitude above the SCOs.

At Complex B, there were no reported concentrations of pesticides, PCBs, or metals that exceeded the Protection of Groundwater SCOs.

A comparison of the analytical results with the Soil Background PAH and Metal Concentrations combined with the Unrestricted Use SCOs show that 12 samples have PAH exceedances and two samples have metal exceedances (see Tables 11B and 12B). The PAH exceedances are likely due to the presence of creosote treated piles spaced 4 to 6 feet apart throughout Complex B. The two samples with metal exceedances are samples of FP-B-16S and FP-B-17S, where barium, copper and zinc concentrations were greater than the criteria. The barium concentration at FP-B-17S is 425 mg/kg versus the background concentration of 248 mg/kg. For copper at FP-B-16S, the detected concentration was 154 mg/kg, above the background concentration of 141 mg/kg. Zinc concentrations exceeded the background concentration (5.5 mg/kg) and the Unrestricted Use SCO (109 mg/kg) in both FP-B-16S (274 mg/kg) and FP-B-17S (369 mg/kg).

3.2 Temporary Piezometer Results

To assess groundwater quality beneath the footprint of the MOSF Tanks and to assess whether historic operations have impacted Site groundwater, 9 temporary piezometers were installed beneath the MOSF footprint. These 9 temporary piezometers include 5 piezometers (PZ A-1 through PZ A-5) beneath Complex A and 4 piezometers beneath Complex B (PZ B-1 through PZ B-4). Summary tables of the analytical data are included as Tables 13A and 13B. Figures 9A and 9B show analytical data with respect to the sample locations.

3.2.1 Complex A

Analytical results show that 7 VOCs and 7 SVOCs were detected in Site groundwater above applicable TOGS 1.1.1 GWQS or guidance values. Acetone, benzene, tetrachloroethene, toluene, ethylbenzene, styrene, and total xylenes were the VOCs detected above the GWQS or guidance values at Complex A. Toluene, ethylbenzene, and total xylenes were detected in concentrations that are four to five orders of magnitude above the GWQS and guidance values. These VOCs are typically not indicative of No. 6 fuel oil, especially at these concentrations. The origin of these compounds is likely associated with the FYN Paint and Lacquer VCP site, which is upgradient of Complex A.

Acetone was detected in three of the five samples with one concentration exceeding the guidance values. Acetone is also a contaminant of concern at the Fyn Paint site. The tetrachloroethene concentration is one order of magnitude above the groundwater standard but was reported as an estimated concentration due to the dilution factor associated with the toluene, ethylbenzene and total xylene concentrations. The source of tetrachloroethene, which was detected in only one sample, is not known.

Analytical data results also suggest that Site groundwater has been impacted by SVOCs. Total phenolic compounds (phenol, 2-methylphenol, 4-methylphenol, 2,4-dimethylphenol), benzo[a]anthracene, bis(2-ethylhexyl)phthalate, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, and indeno[1,2,3-cd]pyrene were detected at concentrations above applicable standards and guidance values. Concentrations ranged from 0.27 ug/l (benzo[a]pyrene in PZ A-4) to 75 ug/l (total phenolic compounds) in PZ A-1. Although these compounds are in exceedance of their respective TOGS 1.1.1 groundwater standard and guidance values, the compounds are not indicative of an impact associated with the MOSF tanks due to the absence of naphthalene. Naphthalene is a common indicator of fuel oils. The impacts associated with the polyaromatic hydrocarbons (PAHs) is likely more indicative of urban fill, whereas the phenolic compounds may be indicative of contaminants associated with the creosote piles or possibly

construction and building materials. However, creosote piles were not present at Complex A; thin walled, cast in place 60 ton concrete piles were present under this complex.

3.2.2 Complex B

To assess the groundwater quality beneath Complex B, four temporary piezometers were installed. Analytical results show that 4 VOCs and 12 SVOCs have been detected in Site ground water above applicable TOGS 1.1.1 GWQS or guidance values. VOCs detected above the GWQS/Guidance Values include benzene, toluene, ethylbenzene and total xylenes (BTEX). Although the BTEX compounds are often associated with gasoline, these compounds are also associated with creosote and Complex B contains numerous wood piles which were likely treated with creosote. These compounds are also associated with the upgradient Fyn Paint site, although the distance and cross gradient direction likely rule that property out as a source. Acetone and 2-butanone were also detected, but at concentrations below the TOGS guidance values. These compounds are also associated with the Fyn Paint site.

SVOCs detected in groundwater at Complex B include phenols (2-methylphenol, 4-methylphenol, 2,4-dimethylphenol), naphthalene, acenaphthene, fluorene, phenanthrene, benzo[a]anthracene, bis(2-ethylhexyl)phthalate, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, and indeno[1,2,3-cd]pyrene. The distribution of these compounds at Complex B is generally inconsistent. For example, total phenols were detected in concentrations exceeding the guidance values at PZ-B-1, PZ-B-2, and PZ-B-4 but not detected at PZ-B-3 whereas naphthalene exceeded the guidance values at PZ-B-2, PZ-B-3 and PZ-B-4, but not detected at PZ-B-1 and detected but at an estimated concentration in the PZ-B-1 duplicate sample. Acenaphthene was the only SVOC that exceeded the guidance value in each of the four groundwater samples.

With the exception of the SVOCs with low guidance values (0.002 ug/l), the exceeding concentrations were mostly on the same order of magnitude as the guidance values. However, the total phenols and naphthalene concentrations were two orders of magnitude above the guidance values. Considering the numerous and closely spaced piles at Complex B, the creosote piles are the likely source of those compounds.

4. CONCLUSIONS

The Site soil encountered during this investigation largely consists of urban fill. The analytical data for VOCs, SVOCs, pesticides, PCBs and metals are generally consistent with the chemical composition of urban fill or associated with creosote treated piles, which exist at Complex B. At Complex A, there appears to be two primary areas where elevated concentrations were detected.

One area is at the southeast corner of the complex, near the intersection of North First Street and River Street. A second area is near the East River, at the northwest corner of Complex A.

Near the southeast corner of the Site, VOCs have been impacted this area by contaminants that appear to be migrating from the Fyn Paint facility. Concentrations of ethylbenzene, toluene and total xylenes are in the double to triple digit part per million (ppm) range in the subsurface sample (FP A-3) collected at the water table in this area. Based on the results of soil samples collected from the surrounding borings (FP A-2, FP A-4, and FP A-5), the impacted area does not appear to extend far onto the Site. However, the groundwater sample collected at PZ A-4, which corresponds with soil sample location FP A-2, shows ethylbenzene and total xylene concentrations that are three and four orders of magnitude above the TOGS 1.1.1 GWQS. Therefore, the impacted groundwater apparently migrating from the Fyn Paint facility does not appear to be fully delineated to the northwest. Groundwater samples collected at PZ A-2 and PZ A-3, which were installed to the west of PZ A-1 have significantly lower concentrations of toluene, ethylbenzene and total xylenes.

Near the northwest corner of the Site, the area appears to be impacted by PAHs as evidenced by certain compounds exceeding the Unrestricted Use SCOs in subsurface soil samples and specifically those samples collected at FP A-16, FP A-21 and FP A-22. These samples are contiguous with respect to the sampling grid and may suggest a separate fill source from the rest of Complex A as no other sample location had PAH concentrations on this order of magnitude. Two other sample locations, FP A-17 and FP A-20, had SVOC exceedances of the Unrestricted Use SCOs (one and two exceedances, respectively). Therefore, the impacted fill appears to be horizontally delineated in this area.

For Complex B, the impacted area appears to be more widespread and less isolated considering 24 of the 40 samples collected have one or more SVOC concentrations that exceed the Unrestricted Use SCOs. Of these, 10 surface soil and 14 subsurface soil samples (24 total) have one or more SVOCs with concentrations that exceed the Unrestricted Use SCOs. Only 12 of the 40 surface and subsurface samples at Complex B have concentrations above the Manhattan background concentrations. These samples include seven surface samples and five subsurface samples.

However, with the exception of acetone at FP-B-3 S DUP (51 ug/kg) and FP-B-17 4.5' (97 ug/kg) and benzene, ethylbenzene and total xylenes at FP-B-11 3.5', no VOC concentrations exceeded the Unrestricted Use SCOs. Also, PCBs were not detected above the Unrestricted Use SCOs. Although a few metals were detected at concentrations exceeding the Unrestricted Use SCOs, only the zinc concentrations in FP-B-16 S and FP-B-17 S, the copper concentration in FP-B-16 S and the barium concentration in FP-B-17 S exceeded the Manhattan Background soil

concentrations. Considering the presence of PAHs and a lack of metals within Complex B, it is believed that the impacted soil is associated with the creosote piles as opposed to the urban fill that exists at this complex. Groundwater analytical data of samples collected from Complex B also supports this conclusion. Total phenols were detected in three of the four groundwater samples collected at Complex B, with concentrations exceeding the TOGS 1.1.1 GWQS. Phenols may be indicative of creosote related impacts.

Data collected during the perimeter investigation also suggests the presence of creosote treated wood as a potential source of Site contaminants. During the perimeter investigation, the SVOCs detected in the B9 sample were reported at higher concentrations in comparison to the remaining sampling locations. The boring log for B9 notes that the 6 to 10 foot interval (bgs) consisted mainly of wood. Boring B9 was near the southwest corner of Complex B and also had exceedances of Unrestricted Use SCOs for SVOCs. Based on historical Site use, it is possible that the wood may have been the remnants of a wooden support pile or railroad tie. The SVOC concentrations in the sample collected at B9 may be indicative of preserved wood and had impacted the sample collected from this boring.

In summary, the reported concentrations for the samples collected during this investigation do not appear to be indicative of any potential release from the MOSF. For the most part with some exceptions, the exceedances are within the same order of magnitude as Part 375 Unrestricted Use SCOs. Based on the analytical data, and meter readings and field observations during this investigation, there is no apparent indication of an impact to soil or groundwater caused by leakage from any of the tanks, ancillary piping, accidental discharges or other Site related activities.

However, it appears that contaminants of concern from the upgradient FYN property are evident at the southeastern side of Complex A, particularly noted by the toluene, ethylbenzene, and total xylenes concentrations detected in the soil and groundwater samples. The presence of these compounds, plus acetone in other samples, in the soil and groundwater suggests migration of impacted groundwater from an upgradient source is occurring. Migration of impacted groundwater is further supported by the historical groundwater sample results of wells installed along the east and south sides of Complex A, where toluene, ethylbenzene, xylenes and other paint manufacturing related chemicals have been detected. Based on the reported concentrations of these contaminants, the impact to groundwater at the Site from activities at the FYN property appears to be significant and continuing migration of the impacted groundwater is ongoing. The predominant migration pathway of these contaminants though the soils is via groundwater movement.

Percent Solids - %	NS	90.8	87.7	91.8	90.3	92.7	92.7	86.1	89.3	88.6	88.3	84.2

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.
* - Surrogate exceeds the control limit for VOCs
* - RPD of the LCS and LCSD exceeds the control limits for VOCs
* - LCS or LCSD exceeds the control limits for VOCs and SVOCs
NR - Analysis not Requested
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
NA - sample was not analyzed for these compounds
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit
* - RPD of the LCS and LCSD exceeds the control limits
* - LCS or LCSD exceeds the control limits
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.
* - Surrogate exceeds the control limit for VOCs
* - RPD of the LCS and LCSD exceeds the control limits for VOCs
* - LCS or LCSD exceeds the control limits for VOCs and SVOCs
NR - Analysis not Requested
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
nd - compound was not detected at the MDL.
NA - sample was not analyzed for these compounds
j - Indicates an estimated value.
b - The analyte was found in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit
* - RPD of the LCS and LCSD exceeds the control limits
* - LCS or LCSD exceeds the control limits
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:

Highlighted cells indicate exceedance of NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and Manhattan, New York background data [1].

Only analytical results that correspond with PAHs and Metals from RETEC Background Report displayed.

1. - RETEC Group, Inc. March 24, 2007. Characterization of Soil Background PAH and Metal Concentrations, Manhattan, New York. Table 4-3a. (PAHs) and Table 4-3b. (Metals)

ND - compound was not detected at the MDL.

NR - sample was not analyzed for these compounds

J - Indicates an estimated value.

B - The analyte was found in an associated blank, as well as in the sample.

P - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit

* - RPD of the LCS and LCSD exceeds the control limits

* - LCS or LCSD exceeds the control limits

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Notes:

Highlighted cells indicate exceedance of NYSDEC Part 375 Unrestricted Use Soil Cleanup Objectives (SCOs) and Manhattan, New York background data.[1.]

Only analytical results that correspond with PAHs and Metals from RETEC Background Report displayed.

1. - RETEC Group, Inc. March 24, 2007. Characterization of Soil Background PAH and Metal Concentrations, Manhattan, New York. Table 4-3a. (PAHs) and Table 4-3b. (Metals)

ND - compound was not detected at the MDL.

NR - sample was not analyzed for these compounds

J - Indicates an estimated value.

B - The analyte was found in an associated blank, as well as in the sample.

P - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.

* - Surrogate exceeds the control limit

* - RPD of the LCS and LCSD exceeds the control limits

* - LCS or LCSD exceeds the control limits

NS - No Standard

NC - Samples not collected for this parameter.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

1. INTRODUCTION

Henningson, Durham and Richardson Architecture and Engineering, P.C. (HDR), on behalf of Consolidated Edison Company of New York, Inc. (Con Edison), has performed a subsurface investigation to assess subsurface conditions at the former North First Street Oil Storage Terminal (NFST) Site. The investigation was performed in accordance with the Site Investigation Work Plan, prepared by HDR and dated March 2011, which was approved by New York State Department of Environmental Conservation (NYSDEC) in a letter dated April 19, 2011 (Appendix A).

1.1 Site Overview

The NFST Site is located in Williamsburg, Brooklyn, Kings County, New York. A Site location map is included as Figure 1. The NFST Site is located in a predominately mixed residential, commercial and manufacturing community. In recent years, the manufacturing demographic has been replaced with mixed residential and commercial properties. Residences are located to the north, across North Third Street. Commercial, light manufacturing are located east across River Street. A New York Power Authority (NYPA) Gas Turbine Generation Station is to the south of NFST.

The Site is zoned as manufacturing district and it was used as a major oil storage facility (MOSF). The NFST Site consists of three lots. The main portion of the Site exists on modern Tax Block 2355, Lot 1 and Tax Block 2361, Lot 1. These lots contain two complexes of aboveground storage tanks. A third lot, Block 2362 Lot 3, contains the office, control room, boiler house, and parking lot. Figure 2 shows the current Site layout including the MOSF structures. Based on the engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer and dated October 4, 1963, these two complexes consist of three tanks each with the following capacities:

- Complex A (southern tanks)
    - T-100 – 6,000,000 gallons
    - T-200 – 2,325,000 gallons
    - T-300 – 6,000,000 gallons
- Complex B (northern tanks)
    - T-400 – 6,000,000 gallons
    - T-500 – 6,000,000 gallons
    - T-600 – 4,950,000 gallons

The ancillary property (boiler/control house) is located at 214 Kent Avenue and is bordered to the north by Metropolitan Avenue, to the south by the Fyn Paint and Lacquer Company (FYN) and to the west by River Street. The ancillary property occupies modern Tax Block 2362, Lot 3 and occupies approximately 0.3 acres.

1.2 Regional Geology/Hydrogeology

The Site is in the Atlantic Coastal Plain physiographic province and is comprised of interbedded layers of sand, clay and marl. The marine deposits are Cretaceous and Quaternary in age. The drift deposits are derived from glacial activity that occurred during the Pleistocene Epoch. The total thickness of the marine and glacial deposits in Kings County ranges from 0 feet in northwest Brooklyn to 1,100 feet thick in northeastern Brooklyn.

The topography of the area slopes to the west towards the East River. The elevation of the Site is approximately 11 to 15 feet above mean sea level (msl). The ground surface at the Site consists of poured concrete and asphalt pavement. The shallow sediments beneath the Site consist of a brown, medium to coarse grained sand with some silt and trace gravel. In general, the subsurface area beneath the Site consists of interbedded layers of sand, gravel, and clay and silt mixture to approximately 75 feet below ground surface (bgs). Bedrock beneath the Site is greater than 75 feet bgs. The regional direction of groundwater flow beneath the Site is to the west, toward the East River.

1.3 Site History and Previous Investigations

Holzmacher, McLendon & Murrell, P.C. (H2M) and HDR (formerly known as Lawler, Matusky and Skelly Engineering, LLC (LMS)) developed background information for the Site on behalf of Con Edison. Background information presented in the *Phase I Environmental Site Assessment Report – Kings County Tax No. Block 2355, Lot 1, Block 2361, Lot 1, Block 2362, Lot 3 & Block 2376, Lot 6 – 214 Kent Avenue, Brooklyn, New York* prepared by H2M and dated September 10, 1999 and *Phase II Site Investigation Report – North First Street Oil Storage Terminal* prepared by HDR and dated January 14, 2000, is summarized below.

A Phase I Environmental Site Assessment (ESA) was performed by H2M for the Con Edison NFST property and the former Pfizer property (currently owned by the New York Power Authority (NYPA)). Based on a review of available records, a number of Recognized Environmental Conditions (RECs) were identified. These RECs included the presence of above-

ground storage tanks (ASTs) and underground storage tanks (USTs) and surface and subsurface soil conditions based on historic Site usage as well as the existence of toxic or hazardous material containers.

At the request of Con Edison, HDR performed a Phase II ESA, as documented in a report dated January 14, 2000. This Site investigation encompassed the NFST Site and the former Pfizer property located to the south of the NFST MOSF facility (between the East River, River Street, Grand Street and North First Street). The Phase II investigation scope included:

- Investigation and sampling of a storm drain outside one of the on-Site buildings and a manhole within another, both located on the former Pfizer property. Results from both of these sample locations indicated that six semi-volatile organic compounds (SVOCs) and eleven metals were detected above the NYSDEC Technical and Administrative Guidance (TAGM) Memo #4046 - Recommended Soil Cleanup Objectives (RSCOs), which were the regulatory criteria in effect at the time of the investigation.

- Thirteen soil borings were advanced into the water table at the former oil storage area and former Pfizer Site. Select samples were collected and sent to a NYSDOH certified laboratory for volatile organic compound (VOC), SVOC, metals, pesticides and PCBs analyses. Laboratory results of the soil samples indicated VOC and SVOC concentrations above the NYSDEC RSCOs. Results for the metal analyses identified ten metals with concentrations above NYSDEC RSCOs. Based on the results, no other analytes were above applicable NYSDEC RSCOs.

- Groundwater samples were collected from four monitoring wells that were initially installed on-Site (MW-1, MW-2, MW-3 and MW-4) as part of the MOSF license issued by NYSDEC. Only one (MW-4) of the four monitoring wells at the Site contained VOCs concentrations in groundwater that exceeded the NYSDEC Class GA standards. Seven metals were also detected above their respective groundwater quality standards while neither SVOCs nor polychlorinated biphenyls (PCBs) were detected in the four monitoring wells.

In addition to the above two documents, a 1996 Con Edison document reported that product containing VOCs was encountered in soil borings advanced for the cathodic protection installation associated with the Con Edison 10,000-gallon UST located in the parking lot at 214 Kent Avenue, adjoining Con Edison's MOSF boiler/control house. The VOCs detected in the product sample included toluene, ethylbenzene and xylenes totaling 876,000 mg/l (milligrams

per liter). NYSDEC Spill Number 96-04977 was assigned to the contamination identified adjacent to the UST. To confirm the 1996 report findings, additional borings were advanced in the vicinity of the UST by HDR in 1999 to characterize the subsurface conditions in this area. This investigation concluded that free phase product was encountered and toluene, ethylbenzene and xylene were detected at elevated concentrations.

In 2001, to assess subsurface soil near the Con Edison UST, Leggette, Brashears & Graham, Inc. (LBG) conducted a limited subsurface investigation associated with the adjacent Fyn Paint facility to the south. The limited subsurface investigation consisted of installing eight soil probes utilizing direct push drilling methods and four groundwater monitoring wells using the hollow stem auger (HSA) method. Of the eight probe borings advanced, four borings were located within the Con Edison Property. Three borings were advanced in the NFST parking lot (CE-1, CE-2, and CE-3), and the fourth boring was advanced along the south side of MOSF Complex B on Metropolitan Avenue (CE-4). The rest of the probe borings were advanced outside the Con Edison property; one was located at the west end of Grant Street (GP-1), one was located on the north side of Complex B on North Third Street (GP-2), and two were located within the Fyn Paint building (GP-3 and GP-4). Laboratory results from this investigation indicated that soil and groundwater within the NFST parking lot was impacted by acetone, ethylbenzene, toluene, and xylene. Subsurface soil concentrations at the borings advanced at NFST ranged from non detect (CE-4) to 3,200,000 ug/kg (xylene at CE-1). Analytical data from Site monitoring wells in this same vicinity confirmed that these VOCs have also impacted Site groundwater. Dissolved phase VOCs were detected at concentrations ranging from non detect (CE-4) to 1,400,000 ug/l (xylene in CE-2). This information is presented in LBG's *Subsurface Investigation and Remedial Action Plan*, dated August 2001 (LBG, 2001).

To better define the limited subsurface investigation, LBG conducted Supplemental Remedial Investigations in 2003, during which all boring and wells were placed in the public right of way. In 2005, LBG expanded its supplemental investigation by installing eight additional groundwater monitoring wells and two extraction wells. VOC concentrations in subsurface soil during this investigation ranged from 19,000 ug/kg at MW-22 (acetone) to 4,000,000 ug/kg of toluene (MW-22). Groundwater concentrations ranged from non detect in CE-4 to 66,000 ug/l of toluene (EW-1). Both MW-22 and EW-1 are within the NFST parking lot. This information is presented in LBG's *Supplemental Remedial Investigation Report*, dated September 2003 (LBG, 2003).

Fyn Paint entered into a Voluntary Cleanup Agreement (VCA) under NYSDEC's Voluntary Cleanup Program (VCP). Under the VCA, LBG implemented an Interim Remedial Measure

(IRM) consisting of a free phase product (solvent) recovery and groundwater extraction system with effluent treatment. The IRM is ongoing with the treatment system located inside the Fyn Paint building and the extraction wells installed in the parking lot area of the ancillary Con Edison facility at 214 Kent Avenue. The IRM system will be decommissioned and replaced with a Dual Phase Extraction (DPE) system as the remediation strategy to be implemented in 2011 following review/approval of the system design by NYSDEC.

2. SITE INVESTIGATION ACTIVITIES

2.1 Field Mobilization/Utility Clearance

Prior to HDR's mobilization to the Site to commence the investigation, Con Edison personnel m-scoped the perimeter of the MOSF to identify subsurface utilities that may interfere with the investigation. To complement this activity, HDR contracted a private utility mark-out contractor, NAEVA Geophysics of Congers, New York, to mark out utilities and other underground anomalies within the work area. To document their markout, NAEVA prepared a map to show the utility runs. This map is included as Appendix B.

A utility clearance was conducted prior to implementing intrusive activities. The procedure entailed utility mark-outs in accordance with the NYS Code 753 process, obtaining and reviewing available utility drawings and a field reconnaissance to verify, to the extent possible, the location of utilities relative to the planned intrusive locations. Aquifer Drilling and Testing, Inc. (ADT) of New Hyde Park, NY, the drilling subcontractor selected by HDR to perform the probe drilling, called in the Code 753 request to proscribed utilities, ADT also secured New York City Department of Transportation (NYCDOT) sidewalk opening permits to advance the probes on City-owned property.

As an added precaution and in accordance with Con Edison's intrusive investigation procedures, the upper 5 feet at each soil boring location was excavated using non-mechanical methods to confirm the absence of utilities (soft dig). ADT was subcontracted to perform non-mechanical clearance at each borehole location. At each location, ADT utilized either hand tools (post hole digger and digging bar), an air knife, or a combination of the two, to excavate to five feet. During intrusive activities, HDR screened the headspace above the excavation with a Genesis combustible 4-gas meter (CGI) to monitor for lower explosive limits (LEL), oxygen, carbon monoxide (CO), and hydrogen sulfide (H_2S). Additionally, stockpiled soils were screened with a photoionization detector (PID) for the presence of any volatile organic compounds (VOCs). Both meters/detectors reported background concentrations of gases at each borehole location during the soft dig.

Soils were classified during soft dig activities and recorded in boring log sheets (Appendix C). Typically, the first five feet of soil consisted of silty sands with varying amounts of brick, asphalt, concrete, gravel and cobbles. Upon completion of each borehole, a five-foot length of 1-inch PVC pipe was placed in the cleared boring location. The PVC pipe was flush to the surface and served as a marker to identify the cleared hole. The excavated material was used to backfill

the excavation. For the borings located in the sidewalk, the top 4 inches was backfilled with cold patch asphalt mix and tamped into place.

2.2 Soil Borings

Eighteen vertical soil borings (B1 through B18) were advanced to assess the subsurface conditions adjacent to the MOSF tanks (Figure 3). The objective of these borings was to physically characterize subsurface soil conditions and allow for the collection of soil samples for laboratory chemical analysis.

ADT was subcontracted by HDR to advance soil borings using direct push technology (DPT) drilling methods and tooling. All borings were advanced continuously in five-foot increments using a 2-inch diameter Macrocore ® barrel with dedicated PVC liners. Each borehole was advanced to the water table.

An HDR environmental scientist was on-Site during the drilling activities to log soils and collect soil samples for laboratory analyses. Soils collected from each boring were described in accordance with the Unified Soil Classification System (USCS). A PID (MiniRAE 2000) and CGI (Thermo Genesis) were used to monitor subsurface soils and headspace of the boring holes. Samples were immediately screened with the PID and CGI to identify areas where volatile organic vapors and/or methane may be present. Observations and field screening data from each boring were recorded on the boring log sheets. No PID readings were noted above background concentrations during soil screening except at borings B-4, B12 and B14. PID responses at these three boring locations were all less than 10 ppm calibration units and were not considered evidence of a release to the environment. PID readings are summarized in Table 1.

In addition to the PID screening, the boreholes were also screened with a CGI. No readings above background concentrations (0% LEL) were noted during the investigation.

Subsurface soils observed during the subsurface investigation were described as silty sand with lower compositions of debris such as brick or concrete. No physical evidence (i.e., staining or odors) of contamination was observed during this investigation. Depths to groundwater ranged from 6.5 to 12 feet bgs.

2.3 Soil Sampling and Analyses

As part of this subsurface investigation, eighteen soil samples were collected immediately above the groundwater table. Upon collection, samples were transferred directly into laboratory-supplied glassware. The portion of the sample collected for VOCs was transferred to the designated sample containers first. In some cases, additional borings were advanced to obtain a sufficient volume of material for analyses. Each container was then labeled with the appropriate sample identification number and sample depth, the analytical parameters to be analyzed, the date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to Test America, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Soil samples submitted to the laboratory were analyzed for VOCs using EPA Method 8260B, SVOCs using EPA Method 8270C (base-neutral compounds only) and Target Analyte List (TAL) metals via EPA Method 6010B. In addition, samples from five selected locations were analyzed for pesticides following EPA Method 8081 and PCBs using EPA Method 8082. These locations were selected to provide a representation of conditions across the Site. Table 2 provides the soil sample analytical summary.

Upon completion of each borehole, sampling equipment (e.g., macrocore sampler) was decontaminated with an Alconox and tap water wash, followed by a de-ionized or distilled water rinse. No drill cuttings were observed to be impacted. Therefore, the cuttings were returned to the subsurface from the holes from which the cuttings were generated.

The location of each boring was surveyed using a global positioning system (GPS) for documentation purposes in case a need to relocate the borehole arose. Due to the proximity of the borings to the tanks, there was a potential that satellite signals would be disrupted, which would distort the plotted location. Therefore, in addition to using a GPS, each location was triangulated using two fixed points such as fire hydrants or manholes. The GPS data and triangulations were used to prepare a figure that most accurately locates each boring (Figure 3).

2.4 Review of Groundwater Sampling Data

In addition to the subsurface soil evaluation, two years of MOSF compliance sampling data and two years of Fyn Paint and Lacquer Company, Inc. groundwater remediation data was also evaluated as part of this Investigation. Monitoring well location associated with the Con Edison MOSF and the Fyn Paint VCP are shown on Figure 4. A summary of the monitoring well

construction details is provided on Table 3. A discussion of the analytical results is provided below.

2.4.1 North 1st Street Major Oil Storage Facility Data (MOSF)

As part of the MOSF annual sampling program, four monitoring wells located in proximity to the tank farm were gauged on a quarterly basis and sampled on an annual basis. These wells are identified as NTMW-1, NTMW-2, NTMW-3, and NTMW-4, but are also referred to as MW-1 through MW-4. Under the MOSF requirements, the samples from these wells were analyzed for SVOCs only, but due to the litigation associated with the Fyn Paint facility, VOCs were subsequently added to the MOSF sampling program. Data dating back to 2005 indicates that the annual MOSF groundwater samples were regularly analyzed for VOCs and SVOCs using EPA Methods SW8260B and SW8270C, respectively, with some earlier sampling rounds that were not associated with the MOSF annual sampling following EPA 624/8260B and EPA 625/8270C analyses. Since 2007, SVOCs were consistently analyzed using EPA Method SW8270B. Only selected analytes were reported in 2011 using EPA Method SW8021 for VOCs and EPA Method SW8270C for SVOCs. Groundwater analytical data for NFST MOSF wells from 2007 forward is provided on Table 4.

NTMW-1, installed as a stick-up protective casing well at the west end of Metropolitan Avenue between the two tank farm complexes, had detections of acenaphthene (0.48 ug/l) and anthracene (0.03 ug/l) during the March 2011 sampling event. However, no other compounds were detected in the 2010 or 2011 sampling events. Although these two compounds were detected at well NTMW-1, the concentrations are significantly below the Class GA guidance value in the Division of Water Technical and Operational Guidance Series (1.1.1) (TOGS 1.1.1) of 20 ug/l for acenaphthene and 50 ug/l for anthracene.

NTMW-2 was installed with a stick-up protective casing at the west end of North First Street. Within the last two years (2010 and 2011), no VOCs nor SVOCs were detected at concentrations above their associated detection limits at MOSF Well NTMW-2.

NTMW-3 was installed with flush mount surface completion near the west end of North Third Street. A sample collected from NTMW-3 had no compounds detected in the March 2010 sampling event. However, in March 2011, several SVOCs were detected. These compounds are summarized in Table 4. NTMW-3 is located between the oil storage facility and a new apartment building, in a publicly accessible area. Due to street cleaning and snow clearing activities, and construction associated with the redevelopment of North 3rd Street and the new

apartment building, the well had been compromised. This monitoring well was repaired in June 2010. The SVOC detections are possibly the result of the compromised well.

NTMW-4 was installed as a flush mount well within the sidewalk along the west side of River Street between Metropolitan Avenue and North First Street. It is the closest MOSF monitoring well to the Fyn Paint and Lacquer building. Several VOCs have been detected in the samples collected from this monitoring well over the past two years. Over this time, twelve VOC compounds have been detected during yearly MOSF sampling events, eight of which have exceeded their associated Class GA Standards or Guidance Values. These compounds are mainly petroleum related (benzene, toluene, ethylbenzene, m,p-xylenes, o-xylene) or chlorinated solvents (trichloroethene, cis-1,2-dichloroethene, 1,1-dichloroethane). Their concentrations (or detection limits if not detected during a particular event) and associated Class GA Standards or Guidance Values are summarized in Table 4. No SVOCs were detected above detection limits in either the March 2010 or March 2011 sampling events. The lack of SVOCs detected in the samples is indicative of the petroleum related VOCs originating from a non-fuel oil source.

2.4.2 Fyn Paint and Lacquer Site

The Fyn Paint VCP groundwater monitoring program initially consisted of quarterly sampling of 30 wells and piezometers for VOCs. However, several wells were subsequently removed from the Fyn Paint monitoring program or reduced to annual sampling due to their distance from the Fyn Paint contamination source. Because of the proximity of these Fyn Paint wells to the NFST MOSF, the data set was reviewed to assess groundwater conditions in the vicinity of the MOSF. Eleven of the Fyn Paint VCP monitoring wells are immediately adjacent to the NFST MOSF. In addition to the four Con Edison MOSF wells (NTMW-1 through NTMW-4), these seven wells also include MW-5, MW-10, MW-12, MW-14, MW-20, GP-2, and CE-4. Although quarterly groundwater samples collected as part of the Fyn Paint VCP investigation date back to February 2008 and seven groundwater sampling events occurred from September 2001 through March 2007, only the data collected in 2009, 2010, and the first quarter of 2011 is summarized herein. Groundwater analytical data for Fyn Paint VCP wells located adjacent to the NFST MOSF wells is provided on Table 5 and a summary of all Fyn Paint VCP wells is included as Appendix D.

Over the past two years, approximately 150 groundwater samples were collected for the Fyn Paint VCP, excluding quality control samples, and analyzed for VOCs following EPA Method 8260. VOCs are the primary contaminants of concern associated with the Fyn Paint site and several VOCs were detected at concentrations in excess of TOGS 1.1.1 Groundwater Quality Standards (GWQS). The predominant Fyn Paint contaminants of concern - acetone, benzene,

toluene, ethylbenzene, and total xylenes - were detected most frequently and at the highest concentrations of the VOCs. Summary tables of historic groundwater sampling data are included as Appendix D.

Acetone was detected at concentrations above the GWQS of 5 µg/l in seven Fyn Paint VCP wells: ASW-1 (sampled one time only), EW-1, MW-15, MW-16, MW-21, MW-24, and MW-28. None of these wells are adjacent to the NFST MOSF and all are located upgradient of the MOSF tanks. Concentrations ranged from 18 µg/l in the ASW-1 sample to 800,000 µg/l in the MW-28 sample, both reported in the June 2010 sampling event. In general, the highest concentrations were recorded during the June 2010 sampling event. In general, concentrations have fluctuated from event to event with the lowest average concentrations being detected in November 2009. According to the LBG report, the decrease noted between June 2010 and September 2010 can be attributed to the start-up of the groundwater pump and treat system at the end of August 2010. However, the variation in concentrations may also be attributed to other factors such as seasonal fluctuations, sampling methods, or hydrogeologic factors. For example, analytical data collected during the first quarter of 2011 show significant increase in VOC concentrations at four monitoring wells (EW-1, MW-16, MW-21, and MW-28). In two of the wells (EW-1 and MW-21), the increase in acetone concentrations from the fourth quarter 2010 to the first quarter 2011 is an order of magnitude. Acetone is not a constituent of fuel oil. It is known to have been used at the Fyn Paint facility.

In the Fyn Paint VCP wells, benzene concentrations in the groundwater samples range from 1.3 µg/l reported in February 2009 at MW-8 to 360 µg/l reported in September 2010 at MW-13. Benzene was also detected in 10 additional wells over the course of the seven sampling events: EW-1, GP-1, MW-6, MW-9A, MW-10, MW-15, MW-16, MW-21, MW-24, and MW-28, each of which is associated with the Fyn Paint VCP. With the exception of MW-10, these wells are either cross gradient or upgradient of the MOSF. The benzene concentration detected in MW-10 was 2.2 ug/l, during the second quarter of 2010. Benzene was not detected in this well during the 7 other quarters in this two year period. During the first quarter of 2011 groundwater sampling event, which is the event with the most recent available data, benzene was detected in three wells (MW-9A, MW-13, and MW-16) with concentrations ranging from 110 ug/l (MW-9A) to 240 ug/l (MW-13). Based on the distribution of the benzene concentrations, the source of the benzene is likely an off-Site source or sources.

Toluene concentrations detected during the Fyn Paint VCP investigation program ranged from 2.6 ug/l at MW-8 in June 2010 to 400,000 ug/l at MW-13 in March 2011. A general comparison of the concentrations detected during the sampling events indicates a slight increase of toluene in

the groundwater quality samples over the past two years. However, until the first quarter 2011 event, the two sampling events in the 3rd and 4th quarters in 2010 indicated a potential decreasing trend. Of the wells immediately adjacent to the MOSF, toluene was most frequently detected in the sample collected from MW-12 with the highest concentration (13,000 ug/l) detected in May 2009. Over the past two plus years, the samples collected from MW-10 in June 2010 and March 2011 (1,100 ug/l and 600 ug/l, respectively), from MW-4 in February 2010 (30 ug/l), MW-12 in March 2011 (3,500 ug/l), MW-20 in March 2011 (5.2 ug/l), and from CE-4 in December 2009 and March 2011 (42 ug/l and 1,500 ug/l, respectively) were the only other detections in the wells immediately adjacent to the MOSF. Considering the toluene distribution, the NFST MOSF does not appear to be a source of this compound.

For the Fyn Paint VCP investigation, the concentrations of ethylbenzene range from 2.2 ug/l as reported at MW-26 in May 2009 to 22,000 ug/l at MW-22 in November 2009. Of the wells immediately adjacent to the MOSF, ethylbenzene was most frequently detected in MW-12, also with the highest concentrations (15,000 ug/l in May 2009 and March 2010). Ethylbenzene was also detected in MW-4 (high of 150 ug/l in March 2011), MW-10 (high of 1,100 ug/l in June 2010), MW-20 (high of 19 ug/l in September 2010), and CE-4 (high of 16 ug/l in March 2011) at concentrations exceeding the GWQS.

The overall concentrations of total xylenes have been decreasing on average over the last two years though the number of detections per sampling event have risen indicating that the concentration of xylenes in the groundwater is becoming more dispersed over time. A maximum concentration of 144,000 ug/l was detected at MW-22 in November 2009 and the lowest detected concentration of 2.1 was recorded at MW-27 in March 2011.

Other compounds that were detected at concentrations exceeding the GWQS in wells adjacent to the MOSF include 2-butanone, cis- and trans-1,2-dichloroethene, 1,1-dichloroethane, 1,2-dichlorobenzene, trichloroethene, and isopropylbenzene. None of these compounds are associated with fuel oil. The source of these compounds is unclear although documentation exists regarding Fyn Paint's use of 2-butanone.

Naphthalene, a common constituent of fuel oils, was not detected in any of the groundwater samples collected in monitoring wells immediately adjacent to the MOSF over this two plus year period.

2.5 Review of Soil Gas Sampling Data

In addition to groundwater results, historic soil vapor data associated with the Fyn Paint VCP was also evaluated. As part of the Fyn Paint VCP, the nearest soil gas point to the NFST MOSF was installed at the northwest corner of North First Street and River Street. The laboratory analytical results of a soil gas sample collected from that point indicated 1,1,1-trichloroethane (TCA) was present in the soil vapor at a concentration of 680 micrograms per cubic meter ($\mu g/m^3$), as presented in LBG's *Soil Vapor Intrusion Investigation Work Plan* (LBG, 2007). Under the October 2006 New York State Department of Health Guidance for Evaluating Soil Vapor Intrusion in the State of New York, TCA concentrations in sub-slab samples are actionable for monitoring or mitigation at 100 $\mu g/m^3$. TCA is not a constituent of No. 6 fuel oil.

3. DISCUSSION OF ANALYTICAL RESULTS

The analytical results of HDR's subsurface soil samples were compared to NYSDEC Part 375 Soil Cleanup Objectives (SCOs) including Unrestricted, Restricted Residential, Commercial, Industrial, and Protection of Groundwater SCOs. Based on the results of the laboratory analyses of the 18 samples, the soils across the Site generally appear consistent in that there is not a wide range of contaminant concentrations. However, in 10 of the 18 samples, some exceedances of certain end use SCOs and Protection of Groundwater SCOs are reported. A summary of the number of soil samples/locations with one or more SCO exceedances is presented in the following table.

Sample Parameter	No. of Samples Collected	Unrestricted Use SCO	Restricted Residential Use SCO	Commercial Use SCO	Industrial Use SCO	Protection of Groundwater SCO
VOCs	18	2	0	0	0	2
SVOCs	18	5	5	1	1	1
Pesticides	5	2	0	0	0	0
PCBs	5	1	0	0	0	0
Metals	18	7	3	3	1	2

Figures 5 through 9 show the locations with exceedances of the Unrestricted, Restricted Residential, Commercial, Industrial, and Protection of Groundwater SCOs. In reviewing the exceedances, the sample locations at the southern wall of Complex B (northern complex) and the northwest corner of Complex A (southern complex) generally have the greatest number of exceedances and the highest concentrations. These samples were collected in boreholes B7, B8, B9, and B10. A summary of the analytical results with comparison to the land use SCOs is presented in Table 6. Table 7 provides a summary of the analytical results in comparison to the Protection of Groundwater SCOs. Table 8 provides a summary of SCO exceedances by individual compounds.

The two VOC exceedances were acetone concentrations in samples collected from borings B12 and B17. These samples exceeded both the Unrestricted Use SCO and the Protection of Groundwater SCO. Boring B12 is the eastern most boring on the south side of Metropolitan Avenue and B17 is approximately mid-block on North First Street, between River Street and the East River. Although the concentrations were below the SCOs, acetone was also detected in borings B13 and B14, which were advanced on the west side of River Street between North First Street and Metropolitan Avenue, and B15 and B16, which were advanced on the north side of

North First Street and east of boring B17. Concentrations of acetone at these locations are indicative of impacted groundwater migrating from the Fyn Paint facility.

Methyl ethyl ketone (MEK), another compound attributable to Fyn Paint, was also detected in the sample collected from B17. However, the MEK concentration (19 ug/kg) was below the SCOs. MEK was not detected in any other sample collected during this investigation.

SVOC SCO exceedances were detected in samples collected from five borings: B1, B7, B8, B9, and B10. With the exception of the samples collected from borings B9 and B10, the concentration of two SVOCs exceeded the SCOs. These SVOC are indeno(1,2,3-cd)pyrene, and dibenzo-(a,h)-anthracene. At B9, seven individual SVOCs were reported at concentrations exceeding the SCOs. The seven SVOC exceedances were compounds that have low SCO concentrations. Only one of the seven SVOCs, benzo(a)pyrene (BaP), had a concentration exceeding the Industrial Use RSCO. Dibenzo(a,h)anthracene and BaP are two of the seven SVOCs with concentrations exceeding the Commercial Use RSCOs. The concentrations of benzo(a)anthracene, benzo(b)fluoranthene, and chrysene exceeded the respective Protection of Groundwater SCOs. At B10, dibenz(a,h)anthracene and indeno(1,2,3-cd)pyrene concentrations exceeded the Restricted Residential Use SCOs. The concentrations of these compounds did not exceed the Protection of Groundwater SCOs.

Naphthalene, a compound that is commonly present in fuel oils, was detected in six of the 18 samples collected. However, no naphthalene concentrations exceeded the SCOs. The highest naphthalene concentration detected during this investigation was 97 ug/kg in the sample collected from boring B16. This concentration is two orders of magnitude below the Unrestricted Use and Protection of Groundwater SCOs.

Results of the metals analyses indicate seven samples with concentrations that exceed the SCOs. These samples were collected from borings B1, B7, B8, B9, B10, B16, and B18. Individual metals with concentrations exceeding the unrestricted use SCOs include arsenic (1 sample), barium (1 sample), chromium (2 samples), copper (5 samples), lead (6 samples), mercury (6 samples), nickel (1 sample), and zinc (5 samples).

Only one metal had a concentration that exceeded the Industrial Use SCOs. That exceedance was for arsenic in the sample collected from B8, with a concentration of 33.7 mg/kg. Four other metal concentrations exceeded the Commercial Use SCOs. These metals included copper in three samples (B8, B10, and B18) and lead in B10. The highest copper concentration during this investigation was 536 mg/kg in the B8 sample. The lead concentration in the B10 sample was

1,140 mg/kg. Two additional metal concentrations, lead in the sample from B8 and mercury in the sample from B10, exceeded the Restricted Residential Use SCOs. With the exception of the samples collected from B8 and B10, no metal concentrations exceeded the Protection of Groundwater SCOs. At B8, arsenic and lead concentrations exceeded the Protection of Groundwater SCOs. At B10, lead and mercury concentrations exceeded the Protection of Groundwater SCOs.

PCB results show one sample, B9, with concentrations above the detection limits. Two Aroclors were detected in this sample, Aroclor 1254 at 160 ug/kg and 1260 at 56 ug/kg. The total PCB concentration of this sample exceeds the Unrestricted Use SCO of 100 ug/kg. The Protection of Groundwater SCO for PCBs was not exceeded.

Concentrations of pesticides in two samples, B5 and B9, exceeded the Unrestricted Use SCOs. At B5, 4,4'-DDT was reported at 4.9 ug/kg, exceeding the Unrestricted Use SCO of 3.3 ug/kg. At B9, 4,4'-DDD and 4-4'-DDE exceeded the Unrestricted Use SCOs of 3.3 ug/kg with concentrations of 3.5 ug/kg and 6.0 ug/kg, respectively. The Protection of Groundwater SCOs for pesticides were not exceeded.

4. CONCLUSIONS

The analytical data for subsurface soil samples collected for this investigation are generally consistent with the chemical composition of urban fill. The SVOCs detected in the B9 sample were reported at higher concentrations in comparison to the remaining sampling locations. The boring log for B9 notes that the 6 to 10 foot interval (bgs) was predominantly wood. Based on historical Site use, it is possible that the wood may have been the remnants of a wooden support pile or railroad tie. The SVOC concentrations in the sample collected at B9 may be indicative of preserved wood and had impacted the sample collected from this boring.

The reported chemical concentrations at the other boring locations do not appear to be indicative of a release of No. 6 fuel oil from the NFST MOSF. For the most part, the exceedances are within the same order of magnitude as the Part 375 Unrestricted Use SCOs. Based on the analytical data, meter readings and field observations during this investigation, there is no apparent indication of impacts to soil caused by leakage from any of the tanks, ancillary piping, accidental discharges or other Site activities.

However, it appears that contaminants of concern from the upgradient FYN property are evident in subsurface soil at the perimeter of the Complex A tank farm, particularly noted by the acetone concentrations detected in the B12 and B17 soil samples. These concentrations exceed NYSDEC Part 375 Unrestricted Use SCOs. The presence of acetone in the soil suggests migration of impacted groundwater is occurring from the upgradient source at the Fyn Paint facility. Migration of impacted groundwater is further supported by the historical groundwater sample results of monitoring wells installed along the east and south sides of Complex A, where toluene, ethylbenzene, xylenes and other paint manufacturing related chemicals have been detected. Based on the reported concentrations of these contaminants, the impact to groundwater at the NFST MOSF Site from activities at the FYN property appears to have occurred and migration of the impacted groundwater is ongoing. The predominant migration pathway of these contaminants through the soils is via groundwater movement.

BOREHOLE SUMMARY
SITE INVESTIGATION REPORT
WESTERN PORTION OF NORTH FIRST STREET OIL STORAGE TERMINAL
49 RIVER STREET
BROOKLYN, NEW YORK

Boring Number	Approximate Location	Boring Depth (ft.)	Depth to Water (ft.)	PID Readings	Depth of Highest PID Reading	Notes
B-12	South side of Metropolitan Avenue, along Tank 300, approximately 85 feet west of the intersection of Metropolitan Avenue and River Street	10	9	ND - 0.3	5' - 7.5'	
B-13	Adjacent to the Southwest corner of Metropolitan Avenue and River Street, alongside northern 1/3 of Tank 300	10	10	ND		
B-14	Adjacent to the Northwest corner of North 1st Street and River Street, alongside southern 1/3 of Tank 300	15	12	ND - 7.8	13' - 15'	
B-15	North side of North 1st Street, along Tank 300, approximately 70 feet west of the intersection of River Street and North 1st Street	10	9	ND		
B-16	North side of North 1st Street, along Tank 300, approximately 125 feet west of the intersection of River Street and North 1st Street	10	9.5	ND		
B-17	North side of North 1st Street, along Tank 200, approximately 185 feet west of the intersection of River Street and North 1st Street	10	9	ND		Slight Petroleum Odor
B-18	North side of North 1st Street, along Tank 100, approximately 240 feet west of the intersection of River Street and North 1st Street	10	7	ND

Table 4
ANALYTICAL RESULTS FOR ANNUAL MOSF GROUNDWATER SAMPLING
WESTERN PORTION OF NORTH FIRST STREET OIL STORAGE TERMINAL
49 RIVER STREET
BROOKLYN, NEW YORK

STD	Groundwater Quality Standard
GV	Groundwater Quality Guidance Value
STD[1]	Standard applies to sum of 1,2-, 1,3-, and 1,4-Xylene
STD[2]	Standard is non-detect
ND	Compound not detected in sample
NA	Not Analyzed - in later rounds of groundwater sampling a modified list of analytes was reported
--	indicates no standard or guidance value provided in NYSDEC TOGS (1.1.1)
"< 5"	Italicized numbers with preceding "<" indicate value is non-detect
45	Shaded values indicate exceedance of NYSDEC TOGS (1.1.1) Water Class GA standard or guidance value

A - Data compared to New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1) Ambient Water Quality Standards & Guidance Values & Groundwater Effluent Limitations

Data Source: Consolidated Edison

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
ND - compound was not detected at the MDL.
j - Indicates an estimated value.
b - The analyte was detected in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.
* - Surrogate exceeds the control limit for VOCs
* - RPD of the LCS and LCSD exceeds the control limits for VOCs
* - LCS or LCSD exceeds the control limits for VOCs and SVOCs
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Notes:
highlighted cells indicate exceedances of NYSDEC Part 375 SCOs
ND - compound was not detected at the MDL.
j - Indicates an estimated value.
b - The analyte was detected in an associated blank, as well as in the sample.
p - The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.
* - Surrogate exceeds the control limit for VOCs
* - RPD of the LCS and LCSD exceeds the control limits for VOCs
* - LCS or LCSD exceeds the control limits for VOCs and SVOCs
NS - No Standard
NC - Samples not collected for this parameter.
ug/kg - microgram per kilogram
mg/kg - milligram per kilogram

Re: Site Investigation Work Plan
North 1st Street Fuel Oil Terminal
Brooklyn, NY
MOSF License No. 2-1480

Dear Mr. Thompson:

The New York State Department of Environmental Conservation (the "Department") has reviewed the March 2011 Site Investigation Work Plan by Henningson, Durham & Richardson Architecture and Engineering, P.C. ("Work Plan") The Work Plan has been submitted to satisfy the License No. 2-1480 Special Condition 4a requirement concerning a site assessment proposal prior to facility's permanent closure.

The Department approves the Work Plan modified as follows:

- Soil sample analytical results for VOCs and SVOCs, obtained during investigation, must be compared with Table 375-6.8(a): *Unrestricted Use Soil Cleanup Objectives.* Groundwater sample analytical results for VOCs and SVOCs must be compared with TOGS 1.1.1, for the protection of drinking water (GA Class).The Department does not require analyses for heavy metals, pesticides, and PCBs for this site assessment.

- Additional borings may be required after the removal of aboveground storage tanks upon review of investigation results.

Please proceed accordingly to a conceptual schedule presented in Table 1 of the Work Plan.

Very truly yours,

Leszek Zielinski

Comments
No additional comments.

Receipt
The following field QC sample was received at the laboratory without a sample collection time documented on the chain of custody: TB (220-15461-19). As a result, a sample collection time of 12:00am, on the date of collection, has been used.

Method(s) 3050B, 6010B, 7471A: The following sample(s) was activated for TAL Metals analysis by the client on 5/23/11:B1 (12') (220-15461-1), B10 (7') (220-15461-16), B11 (9') (220-15461-17), B12 (9') (220-15461-18), B13 (10') (220-15461-6), B14 (12') (220-15461-7), B15 (9') (220-15461-8), B16 (9') (220-15461-9), B17 (9') (220-15461-10), B18 (7') (220-15461-11), B2 (9') (220-15461-2), B3 (9') (220-15461-3), B4 (9.5') (220-15461-4), B5 (10') (220-15461-5), B6 (8') (220-15461-12), B7 (7') (220-15461-13), B8 (7') (220-15461-14), B9 (6.5') (220-15461-15). This analysis was not originally requested on the chain-of-custody (COC).

All other samples were received in good condition within temperature requirements.

GC/MS VOA
No analytical or quality issues were noted.

GC/MS Semi VOA
Method(s) 8270C: Internal standard (ISTD) response for the following samples was outside control limits: B12 (9') (220-15461-18), B9 (6.5') (220-15461-15). The samples were re-analyzed with concurring results. The original set of data has been reported.

No other analytical or quality issues were noted.

GC Semi VOA
Method(s) 8081A: The laboratory control sample (LCS) for batch 51079 exceeded control limits for the following analytes: DDE, DDT, Heptachlor. These analytes were biased high in the LCS.

Method(s) 8081A: The capping continuing calibration verification (CCV) analyzed on 5/26/11 at 16:33 on instrument GC8 did not meet criteria on both columns. The associated samples were analyzed twice with similar results.

Method(s) 8082: The capping continuing calibration verification (CCV) analyzed on 5/25/11 at 23:52 on instrument GC-9 did not meet criteria on both columns. The associated samples were analyzed twice with similar results. The second set of data has been reported.

No other analytical or quality issues were noted.

Metals
No analytical or quality issues were noted.

Organic Prep
No analytical or quality issues were noted.

DATA REPORTING QUALIFIERS

Client: HDR Engineering, Inc. Job Number: 220-15461-1

Lab Section	Qualifier	Description
GC/MS VOA		
	U	Analyzed for but not detected.
	J	Indicates an estimated value.
	*	RPD of the LCS and LCSD exceeds the control limits
	B	The analyte was found in an associated blank, as well as in the sample.
GC/MS Semi VOA		
	U	Analyzed for but not detected.
	J	Indicates an estimated value.
	*	LCS or LCSD exceeds the control limits
GC Semi VOA		
	U	Analyzed for but not detected.
	J	Indicates an estimated value.
	*	LCS or LCSD exceeds the control limits
	*	Surrogate exceeds the control limit
	p	The %RPD between the primary and confirmation column/detector is >40%. The lower value has been reported.
	B	The analyte was found in an associated blank, as well as in the sample.

Question	Answer	Comment
Radioactivity either was not measured or, if measured, is at or below background	True	
The cooler's custody seal, if present, is intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	-0.2C/-0.8C
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the sample IDs on the containers and the COC.	True	
Samples are received within Holding Time.	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	False	SEE NARRATIVE
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified	N/A	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
VOA sample vials do not have headspace or bubble is <6mm (1/4") in diameter.	True	
If necessary, staff have been informed of any short hold time or quick TAT needs	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True

1. OBJECTIVE

This Site Investigation report summarizes the methods, results and conclusions of the Phase II environmental site assessment (ESA) of the former North First Street Oil Storage Terminal Site. A work plan dated November 29, 1999 (Appendix A) was prepared by LMS after reviewing previous Phase I documents and other site documentation provided by Consolidated Edison Company of New York (Con Edison). The Work Plan provided the basis for this investigation and was followed through the site investigation. However, based on the site conditions encountered, some deviation from the Work Plan occurred. These deviations are noted in this report.

During the Work Plan preparation, a Phase I report for the site, and associated documentation were reviewed. The Phase I report identified several recognized environmental conditions on the site, generally as that term has been defined by American Society for Testing and Materials (ASTM). The next stage of the ESA process was site sampling to confirm or refute any significant impacted areas existing on the site relative to regulatory standards and guidelines. The work plan was designed to characterize impacted areas. Based on the limited time frame to implement the Phase II ESA, the field efforts were focused on completing the sampling plan as described in the Work Plan. Because the actual turnaround time for the analytical results became much longer than planned, there was no opportunity to collect additional or delineation samples.

2. BACKGROUND

2.1 SITE DESCRIPTION

The North First Street site is bordered by North 3rd Street to the north, the East River to the west, Grand Street Park and Grand Street to the south, and River Street to the east. A portion of the site is bounded by Metropolitan Avenue to the north, River Street to the west, Kent Avenue to the east, and an adjoining warehouse property to the south. The site consists of two blocks containing large, above ground, oil storage tanks, one block containing the former Pfizer property to the south, and a partial block with a building containing offices, a boiler room, and control room with an adjacent parking lot to the south. The former Pfizer property was previously used for transfer and storage of molasses and sulfuric acid for cough syrup production.

The site topography slopes from east to west with the surface elevations ranging from 10 to approximately 30 feet above mean sea level. No surface elevations were provided on the USGS topographic map for this area (Brooklyn, NY, 1975).

Information provided in the Phase I report (FW, 1999) indicates the site is approximately 400,515 square feet (9.19 acres), of which 156,420 square feet (3.59 acres) is shown as underwater between the bulkhead and the westernmost land surface. The site is currently zoned for heavy manufacturing (M3-1), allowing for heavy industrial uses. Neighboring land use is essentially manufacturing and warehouse operations. Historic use of the property as well as current and past use of adjacent properties are documented in the Phase I Report (H2M, 1999).

Based on the proximity of the site to the East River, groundwater at the site is expected to flow westward. However, the nature of the fill material at the site, which may include buried foundations or footings, may produce local deviations and stagnation areas in the groundwater flow.

2.2 PREVIOUS INVESTIGATIONS

In 1992, prior to Con Edison purchasing the Pfizer property, H2M Group prepared a Phase I Site Assessment Report (Holzmacher, McLendon, and Murrell, P.C. (H2M), 1992). Miller Environmental Group, Inc. (Miller) prepared a subsurface investigation report of the former Pfizer property dated July 16, 1993 preceding the property transfer to Con Edison. Miller also prepared a monitoring well installation report (dated September 1994) for the site to comply with the terms of a Major Petroleum Facilities License issued by NYSDEC. Groundwater sampling of these wells has been documented by laboratory reports. A second Phase I report was prepared by H2M that assessed the entire Con Edison property; it was dated September 10, 1999. Con Edison also has some internal documents that discuss other site sampling activities and results.

The 1992 Phase I report identified four (4) above ground storage tanks (ASTs) and two (2) underground storage tanks (USTs). The ASTs consisted of 2,000,000 gallon and 3,000,000 gallon molasses storage tanks, a 100,000 gallon sulfuric acid tank and a 10,000 gallon molasses holding tank. Reportedly, the molasses tanks contain residual molasses. The contents of the sulfuric acid tank were removed, pipes washed and neutralized with soda ash and the material disposed off site. No discussion of the interior of the holding tank was provided. The USTs included a 2,000 gallon fuel oil tank located at the southeast corner of the former Pfizer property and a 550 gallon tank located at the northern portion of the Pfizer property. The fuel oil tank supplied the boiler for heating molasses prior to transfer from the ASTs. This tank was filled with sand and abandoned in place outside the current Con Edison property as Con Edison no longer owns this corner area. The 550 gallon tank was reportedly at the northern section of the Pfizer property as identified on historic site maps. No discussion was provided regarding the material stored in this tank.

Other areas of potential concern identified in the Pfizer Phase I report include disposal of mycelium at the northeast section of the Pfizer property, some buried heating coils from a sulfuric

acid barge, and a lead lined containment basin in the sulfuric acid loading building. The mycelium waste may have contained ferro-cyanides and metals and was approximately 100 cubic yards. The location of the buried heating coils was not known. The lead lined containment basin was used to limit migration of sulfuric acid during truck loading activities.

Miller prepared a Site Investigation Report (Miller, 1993) that documented their soil, groundwater and sediment sampling of the former Pfizer property. Soil and groundwater samples were collected from seven (7) locations and sediments were collected at three (3) locations. Arsenic (1 sample), chromium (4 samples), copper (4 samples), mercury (6 samples), nickel (3 samples) and zinc (7 samples) were detected (MEG, 1993) in concentrations exceeding the current recommended soil cleanup objectives (NYSDEC Technical and Administrative Guidance Memorandum (TAGM. #4046, 1994) for soils. Other than acetone, which was used in their equipment decontamination, no volatile organic compounds (VOCs) exceeded the NYSDEC recommended soil cleanup objectives. Seven semi-volatile organic compounds (SVOCs) exceeded their TAGM guidance criteria in up to six borings. The groundwater sample analyses showed one boring, B-3, with benzene, toluene, ethylbenzene, and total xylene concentrations exceeding the groundwater quality standards. Boring B-3 was advanced near the northeast corner of the site.

Miller also prepared a monitoring well installation report (Miller, 1994). Four monitoring wells were installed with split-spoon samples collected at five-foot intervals. During the soil sample collection, photoionization detector readings were measured, but no readings above background levels were recorded on the boring logs. The wells were installed from 15 to 20 feet bgs. Groundwater samples collected from these wells have been historically analyzed for SVOCs. According to Con Edison, no SVOCs have been detected in these wells to date.

A Phase I ESA report on the entire Con Edison property, dated September 10, 1999, was prepared by H2M. The Phase I report identified a number of recognized environmental conditions at the site (including some of the concerns previously identified in the Phase I for the Pfizer property):

1. There is a suspected 550 gallon underground storage tank at the northern portion of the Pfizer property and a 2,000 gallon UST near the southeast corner of the Pfizer property that lack appropriate closure documents and may constitute recognized environmental conditions. Documentation or investigation of these tanks may be required.

2. In a December 1992 Phase I document for the former Pfizer portion of the Site, excavation of mycelium and sulfuric acid heating coil-impacted areas was recommended. Reportedly, the mycelium and sulfuric acid impacted areas were excavated to visually clean soils. However, no endpoint samples were collected. Therefore, some shallow soil sampling is planned for this area.

3. The Phase I report stated that asbestos and lead containing paint materials noted at the property were in good condition. Therefore, these materials were not identified as a

significant environmental concern. However, any potential construction or remediation activities should consider these materials.

4. The Phase I report concludes that because the site has a long-term industrial nature and previous site operations are not readily apparent, local impacted areas may be present. Groundwater conditions up and downgradient of the Site, as well as shallow soil conditions, should be investigated. For this reason, several samplings are recommended at locations distributed across the site, rather than in designated source areas. The unknown site history is not a sufficient rationale to constitute a recognized environmental condition in our opinion, but the sampling described above will assess materials present at the site.

5. The Phase I report mentions several containers of toxic or hazardous materials such as diesel fuel, foamite, tar, grease, etc. exist at the Site. Residual materials in storage tanks, such as ethylene glycol and petroleum, and lead containment liners should be properly disposed at an appropriate off site facility.

6. The Phase I report concludes that floor penetrations at the south structure of the former Pfizer property may be potential sources. These locations will be inspected, traced if possible, and sampled if the penetrations discharge to onsite areas.

7. Two elevated stainless steel tanks were discussed in the Phase I report. These tanks are situated in the tank filling structure and contained an unknown liquid. The size of the tanks is also unknown. No evidence of leakage or overfilling was discussed in the Phase I report. Therefore, these tanks will be inspected to evaluate their previous use. If the tanks contain residual materials, the residuals will be sampled, if possible, for waste disposal parameters so that potential remedial actions can be evaluated. Also, the volume of material remaining in the tanks will be estimated for disposal.

8. Information provided by Con Edison has shown that product containing volatile organics was encountered in soil borings advanced for the cathodic protection installation associated with the 10,000 gallon UST. The VOCs detected included toluene, ethylbenzene, and xylenes totaling 876,000 mg/l (Con Edison, no date). The NYSDEC spill number associated with these results is 96-04977. The source of these compounds has not been identified, but is suspected to be the paint company to the south. To confirm these results, borings will be advanced within the vicinity of the UST to characterize the subsurface conditions in this area.

9. An inventory of toxic/hazardous material on site including a material description, location and volume should be performed. This will be useful for formulation of any remedial action.

Based on information provided by Con Edison as reported by NYSDEC spill database, there are four open spill numbers associated with the site. Copies of the DEC Spill cases that remain open are included in Appendix B. A summary of the spill numbers is provided in the following table, and additional information regarding the actual status, as provided by Con Edison, has been added.

Spill Number	Date	Amount spilled	DEC Status/ Comments
9007596	10/10/90	15,000 gallons, #6 fuel	Open/All contained in dike area. Tank repaired and dike cleaned up.
9106388	9/13/91	500 gallons of diesel	Open/ Contained on roof of the storage tank. Vendor cleaned it up.
9412417	12/16/94	200 gallons of #6 fuel	Open/ Contained in the steel moat.
9611792	12/30/96	10 gallons of #6 fuel	Open/ leaked onto concrete. Was cleaned up.

Based on the information regarding the actual status of the above spills, they were either contained or cleaned up. Therefore, these spill cases should be closed by DEC. Additionally based on the investigation results, there appears to be no evidence that fuel oil #6 has caused any impact into soil or groundwater at this site.

3. FIELD INVESTIGATIONS

3.1 GEOPHYSICAL SURVEY

LMS contracted Sub-Surface Informational Surveys, Inc. (SIS) to survey the suspected underground storage tank (UST) areas identified in the Phase I Report (H2M, 1999). The suspect USTs are reportedly a 550 gallon UST at the northern portion of the Pfizer property and a 2,000 gallon UST near the southeast corner of the Pfizer property. The material historically stored in either UST was not provided in the previous documentation. Reportedly, the 2,000 gallon UST was on the portion of the Pfizer property that is now part of Grand Ferry Park and is not part of the Con Edison property. Beeause the location of this UST was uncertain, the geophysical survey included the portion of the Con Edison property adjacent to Grand Ferry Park.

On December 3, 1999, SIS conducted a ground penetrating radar survey capable of identifying anomalies at depths up to 7.2 feet below ground surface (bgs). The survey grid consisted of traverses with a 4 to 5-foot horizontal separation. The first area surveyed by SIS included the asphalt paved access road between the former molasses tank and the south end of the former Pfizer property, near the area where the 2,000 gallon UST was shown. No anomalies were observed by the GPR in this area. The second area surveyed was the northern portion of the Pfizer property so that the suspect 550-gallon UST could be located. Because of heavy brush, the GPR survey could not extend to the extreme rear of the property between the seawall and the existing leveled building foundation. No anomalous readings indicative of a UST were noted

within the area surveyed by GPR. A ferromagnetic magnetometer was used to survey the area that was not accessible by the GPR and, other than the minimum signal from surface metals, no anomalous readings were noted. Therefore, this survey addressed recognized environmental condition (REC) (1), concluding that either no UST existed in this area or it was removed. The surveyed area is shown in a figure in Appendix C (SIS Geophysical Survey Report).

3.2 SAMPLING OF BUILDING AND STRUCTURES

The site now contains three buildings: two (2) one-story buildings on the former Pfizer property and a building containing an office, control room and boiler house at the property adjacent to Kent Avenue. As stated above, asbestos and lead based paint noted at the site are in good condition and REC (3) was not identified as a significant environmental concern in the 1999 Phase I document (H2M, 1999). Therefore, asbestos and lead based paint assessment was not part of the work scope for this investigation. A manhole and two floor drains were identified in one of the former Pfizer site buildings, referred as REC (6). Both the floor drains and the manhole are believed to drain to the East River. The floor drains and the manhole were inspected to document their integrity and probed to assess the bottom conditions. The sediment within the floor drains or manhole was sampled for TCL VOCs, SVOC, pesticides/PCBs, and TAL Metals and cyanide (Table 1).

The samples were collected using both a hand auger and trowel, as appropriate to remove material from the floor drains and manhole. The portion of the sample collected for VOCs was immediately transferred to laboratory supplied sample containers. A photoionization detector or equivalent was used to obtain a headspace reading of the material with no readings above background conditions noted. The remainder of the sample was transferred to decontaminated stainless steel bowls, homogenized, and then transferred to the appropriate containers.

One of the floor drains within the building at the Pfizer property did not contain enough sediment to submit for laboratory analyses. The second floor drain within the building was not sampled during the field activities. However, a storm drain outside the building on the Pfizer property was sampled and identified as D-01. A sample was also collected from the manhole within the building and identified as M-01.

To address RECs (5) and (9), on December 15, 1999, an LMS representative walked the site with Mr. Joe Manfre, a Con Edison employee, to inventory the drums and other containers remaining on site. This site walk included viewing several chemical storage cabinets at the site, touring the inside of the boiler room building, and traversing the open areas of the site.

Several drums and containers were observed in the chemical storage cabinet at the easternmost part of the asphalt parking area adjacent to Kent Avenue. Two empty 55-gallon drums were

Characteristics include reactivity, corrosivity, and ignitability

inside the cabinet whereas one empty 55-gallon drum was outside the cabinet. Three 5-gallon and one 1-gallon containers for gasoline storage were also inside the cabinet, but each of these containers was empty at the time of the site walk. Seven other 1-gallon containers were also inside the cabinet including one full container labeled as cutting oil, one near empty container labeled as denatured alcohol, and five unlabelled containers that were partially full to full. At the rear of the parking lot there were two additional full 55-gallon drums. One drum was labeled as analysis pending and the second as Texaco RN-1030, Regal R&O 32. Mr. Manfre indicated that the second drum is compressor oil and mostly water.

Five 1-gallon paint cans were observed within a chemical storage cabinet situated inside the fence at Metropolitan Avenue. Four empty 55-gallon drums were also observed within the fenced area of Metropolitan Avenue, but away from the storage cabinet. Within the fenced area of North First Street, six empty 55-gallon drums were observed. According to Mr. Manfre, these drums are associated with a contractor's activity at the site. Six additional drums, containing investigative derived waste associated with the activities described in this report, are situated on a drum storage pad within the former Pfizer property.

A chemical storage shed is situated on the former Pfizer property. This shed was not opened during the site walk. According to the Phase I Report dated September 10, 1999 that cites Con Edison personnel, the shed was installed by Con Edison for spare boiler parts and empty 55-gallon drum storage.

The two steel containers within the truck filling facility REC (7) were inspected during the site activities. Although the usage of these containers was not identified during the inspection, the containers are currently empty as determined by sounding the containers. The construction of the containers appears to be thin walled galvanized steel, and not stainless steel as reported in the September 10, 1999 Phase I Report. Therefore, it is not likely that these containers were used to store hazardous materials. The containers are approximately 55-gallons each.

Eleven ASTs were observed at exterior areas of the site, four of which are situated on the former Pfizer property. The former Pfizer property tanks include three tanks for molasses storage and one AST for sulfuric acid storage. According to the Phase I Report dated September 10, 1999 that cites conversations with Con Edison personnel, the sulfuric acid tank is empty and removed from service before transfer of the property to Con Edison. The capacities of the three molasses ASTs are 2 million gallons, 3 million gallons and approximately 20,000 gallons. According to Con Edison personnel, as cited in the Phase I Report (H2M, 1999), the two larger tanks were removed from service before transfer of the property to Con Edison. Reportedly, between 18 and 24 inches of molasses remain in these tanks. The 20,000 gallon tank is elevated above a one story structure and was used to temporarily store heated molasses before transfer to trucks for transport (H2M, 1999). During the site activities, this AST was observed to be hard piped to the larger

molasses storage tanks and it was not readily accessible. A pressure gauge installed in the piping indicated no pressure in the piping.

The remaining seven exterior ASTs observed onsite include the six tanks that were previously used for fuel oil storage. As cited in the Phase I report (H2M, 1999) these tanks are out of service and have been certified as gas free. The remaining exterior AST is a condensing tank located west of the boiler house.

Interior ASTs include a 234-gallon tank used to store fuel oil for the emergency backup generator and a 3,000-gallon tank that was used to store 3% foamite (ethylene glycol) for fire suppression. Because these are ASTs and were observed to be in good condition, these tanks are not currently a recognized environmental concern.

3.3 SURFACE SOIL SAMPLING

Because ASTs, existing buildings, and asphalt paved areas cover the majority of the site, surface soil samples were not collected. During the test pit operations for clearing the upper 5 feet for borehole advancement, the entire 0 to 5-foot bgs interval was inspected to identify any potential environmental impacts and samples were collected if deemed necessary. Eight samples were collected from the 0 to 4 feet bgs interval after the material was exposed prior to borehole advancement. The sample collection is described in Section 3.4.2 below with results presented in Section 4. The objective of the surface soil sampling was to partly assess the long term industrial nature of the site including previous site operations described as REC (4).

3.4 SUBSURFACE SAMPLING

3.4.1 Site Set Up

Prior to the commencement of the subsurface investigation, Eastern Locating (Eastern) was contacted to mark the utilities at the site. On November 30, 1999, Eastern used m-scopes or similar devices in an attempt to identify the orientations of potential utilities near the proposed subsurface sampling locations. A LMS representative was on site during the utility mark out so that any potential changes in borehole locations could be made if necessary to ensure utility clearance. After the subsurface utilities were marked, LMS directed the excavation of the upper 5 feet at each borehole location. These 5-foot excavations were advanced by soil vacuuming and hand digging. LMS contracted Allstate PowerVac (Allstate) of Brooklyn, NY to complete the hand digging and soil vacuum excavations. Allstate was on site from December 2, through December 8, 1999 excluding weekends.

3.4.2 Soil Borings

From December 2 through December 10, 1999, thirteen (13) borings were advanced at the site (Figure 1) using a mobile AMS drill rig provided by LMS. An LMS inspector directed the driller to advance sample tubes for soil collection. The probe samples were advanced using a truck mounted probe unit using a direct push hydraulic hammer system. Soil samples were collected in 4-ft intervals, using a 1.5-in. inside diameter (ID) macro core soil sampler. The sampler was hammered to the desired sampling depth using the hydraulic system. Soil cores were recovered in dedicated acetate liners that were fitted with a steel sampler prior to advancement. Upon removal from the sampler, the soil was placed into laboratory cleaned sampling jars if impacted material was observed, odorous or was otherwise suspected to be present. The head space of the sample jar was screened using a PID after a short period of time. PID readings were noted on the boring log with sample interval, soil description, moisture content, color and evidence of potential impacts (odor, sheen). Completion depths and field observations during the drilling activities are documented in the geologic logs (Appendix D). Locations of the borings advanced at the site are shown on Figure 1. The objective of advancing each boring for sample collection was provided in the Work Plan (Appendix A).

Soil samples were placed in glass jars and labeled with the appropriate site name, job number, sample location/identification, date, time, sampler, and parameters for analysis. Additional samples were collected continuously at lower depths unless refusal limited recovery. Refusal was encountered in only one boring, B-5 at 8 feet bgs. Each additional sample was collected using new acetate liners and the same sampling protocol described above. Upon encountering the completion depth, the borehole was backfilled to grade level.

Wall scrapes were collected from the 0 to 4 foot bgs interval if staining, odors or other evidence of a potential impact was observed. The 0 to 4 feet bgs interval was sampled at eight boreholes including borings S-02, S-05, S-06, and S-09 through S-13. Wall scrape and subsurface samples collected at borings S-06 and S-09 through S-13 were advanced to assess the long term industrial nature and previous site operations at the site.

Upon removal from the borehole, the samples were described, field screened using a PID. This information has also been recorded on the geologic logs. If appropriate, a portion of the sample was composited and transferred to laboratory-provided sample containers. Samples transferred to containers were either collected at the water table or at intervals that showed some evidence that the material was impacted. These samples were submitted to Environmental Testing Laboratories (ETL), a New York State certified laboratory, for analyses. A summary of all samples collected for laboratory analyses including the date collected and requested parameter is provided in Table 1. According to the Work Plan for this site, at least one and a maximum of three samples were to

be collected at each boring. However, four samples were collected at borings S-2 and S-4 because of the impacted soil conditions encountered during the drilling.

PID readings above background levels were measured only in the borings advanced within the asphalt parking area adjacent to Kent Avenue (REC 8): borings S-01, S-02, S-03, and S-04. At S-01, the highest PID readings were measured from the samples collected at 8 to 12 feet bgs and 12-16 feet bgs. In both intervals, the PID reading was 500 parts per million (ppm). At S-02, the highest PID reading (750 ppm) was measured in the 12 to 16 foot bgs interval. The 8 to 12 foot bgs interval also had an elevated reading, peaking at 500 ppm. At S-04, the highest PID reading was measured in the 12 to 16 foot bgs interval (650 ppm). Elevated readings were also measured in the 16 to 20 foot bgs (500 ppm) and 8 to 12 foot bgs (10 ppm) intervals. At boring S-03, elevated PID readings were also measured, but the readings were not as high as measured in the other three borings advanced in this area. The highest reading measured at S-03 was 200 ppm in the 12 to 16 foot bgs interval, although the 8 to 12 foot bgs interval also had a reading of 50 ppm. No other samples collected at the site had elevated PID readings. All PID readings were recorded on the appropriate geologic logs (Appendix D).

As a result of the PID readings at S-02 and the strong odors noted, Con Edison notified NYSDEC of the observations on December 10, 1999. An environmental detailed incident report was prepared (Incident ID 129261), noting that a spill of an unknown fluid was observed next to a paint factory. A previous report (Spill # 96-04977) was submitted to NYSDEC on July 15, 1996 following sample collection within 30 feet of the S-02 boring. The amount of spill noted in the report was 1 ounce.

Because four (4) monitoring wells currently exist at the site (Figure 1), no additional permanent groundwater monitoring wells were installed. However, groundwater samples were collected from the exiting monitoring wells and selected borings as discussed in the following section.

During the site set-up, a decontamination pad and a drum storage pad were constructed. All downhole equipment that was exposed to potentially impacted materials was decontaminated before re-use at another location. Decontamination procedures consisted of washing the downhole drilling equipment with a non-phosphate soap and water wash followed by a distilled rinse. Sampling tools used to transfer the sample from the split spoon to the sample jars were lab decontaminated before the site activities. The decontamination fluids were transferred to 55-gallon drums provided by Con Edison.

Locations of all soil borings were measured from existing and permanent site features. The measurements were collected in a way so that each location can be revisited if necessary. The measurements were recorded in a field logbook or on a boring log as appropriate. No formal survey of sample locations and elevations occurred.

3.4.3 Groundwater Sampling

Groundwater samples were collected from borings S-01, S-02, S-04, S-06, and S-08 using a disposable driving point and screen with the AMS Power Probe. A summary of the analytical protocol is included as Table 1. When the desired sampling interval was reached, the 1.5 inch outer diameter rods were pulled back two feet to allow the disposable point to become detached from the rods. The bottom of the rods has a screen that allows groundwater to infiltrate past the screen up inside the rods. Dedicated polyethylene tubing with a check valve and ball bearing was lowered inside the rods. The water was transported to the surface through the tubing and transferred to the appropriate sampling jars.

Groundwater samples were initially proposed for collection at S-1, S-2, S-3, S-4, S-5, and S-6. However, the groundwater samples were collected at S-1, S-2, S-4, S-6, and S-8. With the exception of sample S-06, each sample was identified by a "W" followed by the borehole number.

Upon completion of each boring, a decision was made as to whether to collect a groundwater sample from the boring based on PID readings, observations of the samples collected and whether any odors were noted. A sample was not collected from S-3 because the PID readings were not as high in this boring as compared to other borings advanced in this area. At S-5, a sample was not collected because refusal was encountered and there was no evidence of potential impacts associated with the 2,000 gallon UST that previously existed near this area. S-5 was advanced to a depth (8 feet bgs) that would generally be coincident with the bottom of an UST. However, a sample was added at the S-8 boring to assess groundwater conditions near the sulfuric acid tank and the mycelium disposal area described as REC (2).

With the exception of the sample collected at S-4 (identified as W-4), all samples were analyzed for VOCs, SVOCs, pesticides/PCBs, filtered and unfiltered TAL metals. The W-4 sample was submitted for VOCs only because of the slow recharge rate at this boring. Table 1 lists the boring number, sampling date, and sample parameters for both soil and groundwater sampling.

Because this site has four existing monitoring wells, no new monitoring wells were installed. However, groundwater samples were collected from these existing wells to assess groundwater conditions at the site. Historic sample results from Con Edison annual groundwater testing provided data for base neutral compounds for these wells with the results indicating low levels or no detectable concentrations of the compounds being detected. However, the annual testing did not include VOCs or other parameters. Therefore, to assess the groundwater at these areas of the site, the groundwater samples were submitted for VOCs, SVOCs, pesticides/PCBs, metals and cyanide analyses. A 2-inch diameter, stainless steel Grundfos pump was used to purge the

monitoring wells before a disposable polyethylene bailer was used for the sample collection. Well sampling logs are included as Appendix E.

The sampling activity commenced by opening the well and immediately collecting a headspace reading to assess any vapors that may be present. A depth to groundwater measurement was then collected to determine the groundwater elevation and the amount of water to be removed for each well volume. Each well was be purged of at least three (3) well volumes before the groundwater samples are collected. The purged groundwater was contained in 55-gallon drums and handled following the waste handling procedures described in the Work Plan. Following purging, the wells were allowed to recover until either 90% of the initial static water level or two (2) hours after completion of purging, whichever occurred first. Groundwater samples were collected by lowering the dedicated polyethylene bailer below the water surface and then raising it from the well. The VOC containers were filled first, followed by SVOCs, pesticides/PCBs, and metals/cyanide. A trip blank for VOCs accompanied the sample containers from the laboratory through the field sampling and delivery to the laboratory. A blind duplicate sample identified as MW-5 was also collected from MW-4. Samples were also collected for matrix spike/matrix spike duplicate (MS/MSD) analyses from this well. However, the laboratory analyzed the samples for total concentrations rather than the MS/MSD analyses.

3.5 SURFACE WATER SAMPLING

During the field activities, the bulkhead was inspected at low tide for any visual discharges including sheens or discolored leachate. No visual discharges were noted during the bulkhead inspection. Therefore, in accordance with the Work Plan, no quantitative surface water sampling occurred.

3.6 SEDIMENT SAMPLING

Because no visual discharges were observed, no sediment samples were collected from the perimeter of the site. In addition, as per the Work Plan, this investigation focused on the site and not the adjacent waterway. Sediment samples were collected from the East River during a previous investigation (Miller, 1993). The results of these samples showed that sediments have the common constituents of the East River sediment.

A manhole within the truck weighing structure was sampled using a four foot acetate liner. The liner was lowered into the hole and the sample was collected inside the liner that was immediately collected for VOCs. A storm drain (D-01) just outside of the truck weighing structure located to the north between the building and the larger tank (110 foot diameter) was sampled using the same method. The approximate locations of the manhole and storm drain are shown on Figure 1. The purpose of the sediment samples is to assess the nature of materials that

may have accumulated or passed through the drainage system during the previous site operations.

The material was then be transferred to a decontaminated stainless steel bowl, homogenized and transferred to the appropriate laboratory supplied sample containers for SVOCs, pesticides/PCBs, and metals analyses. All equipment that has come in direct contact with the material that was sampled was decontaminated before re-use.

3.7 SAMPLE HANDLING

The sampling activities discussed in this report followed the procedures described in the QA/QC plan for this site. All materials that were sampled were transferred to laboratory supplied sample containers immediately following collection. In general, the portion of the sample collected for VOCs was transferred to the sample containers first to minimize any potential loss of VOCs. Upon collection, each container was labeled according to the sample identification. The parameter, date, time, person collecting the sample, preservative and site location were also indicated on the sample container label. The sample containers were then placed in an iced cooler maintained at 4° Celsius. An ETL chain of custody was prepared to track the sample containers from collection through delivery to ETL. Sample coolers were secured with chain of custody seals. All sample coolers were delivered to the ETL by overnight courier. Bubble wrap or other packaging materials to limit potential container breakage protected all samples submitted to the laboratory. Coolers forwarded by overnight courier were adequately secured with packaging tape to prevent the cooler from opening during shipment.

As per the Work Plan for this site, LMS collected some samples for matrix spike matrix spike duplicate (MS\MSD) analyses. However, after some of the work had been initiated at the site, Con Edison requested that the MS\MSD samples be removed from the analytical protocol. Because some samples had already been collected and submitted for these analyses, the laboratory analyzed these samples for total analyses without performing the requested MS\MSD analyses. The total analyses of these samples, as reported by the laboratory, are included in this report.

4. SAMPLE RESULTS

All laboratory analytical results discussed herein are from final data that was supplied by ETL to meet the schedule for this investigation. The data (Appendix F) has been QA\QC reviewed and is final. Therefore, the QA\QC of the data incorporated in this report has been validated by ETL.

4.1 SOILS

Results of the volatile organic compound analyses (Table 2) show total VOC concentrations ranging from not detected in the sample collected from 4 to 8 feet bgs at S-12 (S-12B) to 25,695 mg/kg in the sample collected from 12 to 16 feet bgs at boring S-02 (S-02D). Total VOC concentrations exceeded the NYSDEC recommended soil cleanup objectives (10 mg/kg) in 9 samples. With the exception of one sample (S-09B), all of these exceedances were from samples collected in the asphalt parking area adjacent to Kent Avenue. Exceedances were detected in all of the four borings advanced in this area. In general, the highest total concentrations were detected in the sample collected from 12 to 16 feet bgs at each boring. Groundwater was first encountered at approximately 14 feet bgs in each of the four borings advanced in this area. Samples were also collected below the groundwater table at S-01 and S-04 (16 to 20 feet bgs) with the total concentrations decreasing with depth. However, the total VOC concentration (88.8 mg/kg) detected at this interval in the S-04 boring (S-04E) remained above the cleanup objective. The individual VOCs that were detected above their respective cleanup objectives include the following:

Compound	Cleanup Objective (mg/kg)	Total Exceedances (of 33 samples)	High Concentration (mg/kg)	Sample Location of High Exceedance
Acetone	0.2	5	191	S-04, 12-16
Methylene Chloride	0.1	6	2.73	S-02, 12-16
1,1,1-Trichloroethane	0.8	2	2.43	S-02, 12-16
Benzene	0.06	2	0.491	S-02, 12-16
Trichloroethene	0.7	1	0.726	S-02, 12-16
Toluene	1.5	7	4,900	S-02, 12-16
Tetrachloroethene	1.4	2	9.35	S-02, 12-16
Ethylbenzene	5.5	8	3,350	S-02, 12-16
m,p-xylene	1.2	10	13,700	S-02, 12-16
o-xylene	1.2	6	3,640	S-02, 12-16

The primary VOCs that led to the total concentration exceedances were benzene, toluene, ethylbenzene, and xylenes (BTEX). These constituents are consistent with a liquid sample collected by others during the cathodic protection installation for the tank although lower in concentration. The total BTEX concentration previously detected in the sample collected from this area was 876,000mg/l (Con Edison fax from J. Manfre to Mariela Gonzalez, no date).

At S-02, 1,1,1-trichloroethane and tetrachloroethene (PCE) were detected in the samples collected from 8 to 12 (S-02C) and 12 to 16 feet (S-02D) bgs samples. Trichloroethene (TCE) was detected in one sample, S-02 from 12 to 16 feet bgs (S-02D). These compounds were detected in concentrations exceeding the cleanup objectives by an order of magnitude or less and were not detected in any other soil samples collected during this site investigation. Acetone (at S-01 and

NR - Not run.
SB - Site background.
Note: - Numbers in bold exceed cleanup objective.

S-04) and methylene chloride (at S-02, S-03, and S-04) were also detected in some of these samples with concentrations exceeding the cleanup objectives. However, both compounds are common laboratory artifacts or associated with equipment decontamination. Other VOCs detected in the soil samples were reported in concentrations below the cleanup objectives.

The remaining sample that exceeded the total VOC concentration cleanup objective, S-09B, was collected near the northeast corner of the former Pfizer property, in the area where the mycelium waste was disposed. Constituents above the cleanup objectives at this location include toluene, ethylbenzene, and xylenes. This location is downgradient of the asphalt parking area and the constituents may be associated with migration of the BTEX constituents of that area. In comparison to the soil samples previously collected by MEG in 1993 (Boring B-3), the BTEX concentrations have increased at least 3 orders of magnitude.

Acetone (0.218 mg/kg) was also detected slightly above the cleanup objective (0.2 mg/kg) in the sample collected from the 4 to 8 foot bgs interval of boring B-6. No other VOCs were detected in concentrations exceeding the cleanup objectives in samples collected at B-6. At borings B-5 (near former 2,000 gallon UST), B-7 (historic fill at former Pfizer property), B-8 (downgradient of the sulfuric acid AST), B-10, B-11, B-12, and B-13, no VOCs were detected in the soil samples at concentrations exceeding the cleanup criteria. Borings B-10 through B-13 were advanced adjacent to the fuel oil storage ASTs.

The soil cleanup objectives for total SVOC concentrations (500 mg/kg) was not exceeded in any soil samples collected during this investigation. The highest detected total SVOC concentration (61.2 mg/kg) occurred at the sample collected at boring S-06 from 4 to 8 feet bgs. This sample also had concentrations of six individual SVOCs exceeding their respective cleanup objectives. The individual SVOCs that were detected above their respective cleanup objectives include the following:

Compound	Cleanup Objective (mg/kg)	Total Exceedances (of 33 samples)	High Concentration (mg/kg)	Sample Location of High Exceedance
Phenol	0.03 or MDL	17	0.887	S-02/0-4 ft bgs
2-methylphenol	0.1 or MDL	9	0.91	S-04/12-16 ft bgs
Pentachlorophenol	1.0 or MDL	1	0.464	S-06/0-4 ft bgs
benzo(a)anthracene	0.224 or MDL	11	4.61	S-06/4-8 ft bgs
Chrysene	0.4 or MDL	7	4.69	S-06/4-8 ft bgs
benzo(b)fluoranthene	1.1	4	3.67	S-06/4-8 ft bgs
benzo(k)fluoranthene	1.1	4	3.74	S-06/4-8 ft bgs
benzo(a)pyrene	0.061 or MDL	12	4.4	S-06/4-8 ft bgs
dibenzo(a,h)anthracene	0.014 or MDL	6	0.516	S-06/0-4 ft bgs

As shown by the data in the above table, the exceedances are generally an order of magnitude or less than the cleanup objectives. Of the 33 samples collected, only 11 samples had at least three SVOCs detected in concentrations exceeding the cleanup objectives and 7 had four or more SVOC exceedances. These seven samples include S-02 from 0 to 4 feet bgs (7), S-03 from 12 to 16 feet bgs (4), S-05 from 0 to 4 feet bgs (5) S-06 from 0 to 4 feet bgs (8), S-06 from 4 to 8 feet bgs (6), S-07 from 0 to 4 feet bgs (4), and S-12 from 4 to 8 feet bgs (4) with the number in parentheses indicating the SVOC exceedances for that sample.

Only eight samples had detectable PCB concentrations. However, the total PCB concentrations were below the soil cleanup objectives (10 mg/kg). PCB Aroclor 1260 was detected in only one sample, S-06 from 0 to 4 feet bgs, at 0.0311 mg/kg. Aroclor 1248 was detected in the remaining seven samples with a high concentration in the sample collected from the 12 to 16 foot bgs interval at boring B-01 (2.06 mg/kg). PCBs were detected in three of eight surface or near surface samples (0 to 4 feet bgs) with the highest concentration (0.369 mg/kg) detected at S-10. This concentration is below the surface soil cleanup objectives for PCBs (1.0 mg/kg). Pesticides were not detected in any samples collected at this site during this investigation.

Results of the metals analyses showed concentrations of ten metals exceeding the cleanup objectives. A summary of these metals is included in the following table.

Metal	Cleanup Objective (mg/kg)	Total Exceedances (of 33 samples)	High Concentration (mg/kg)	Sample Location of High Exceedance
Arsenic	7.5 or SB	4	36.9	S-06/0-4 ft bgs
Beryllium	0.16 or SB	31	0.62	S-04/8-12 ft bgs
Cadmium	1 or SB	7	4.64	S-02/0-4 ft bgs
Chromium	10 or SB	29	133	S-11/0-4 ft bgs
Copper	25 or SB	8	573	S-03/4-8 ft bgs
Iron	2,000 or SB	33	38,400	S-02/0-4 ft bgs
Mercury	0.1	14	3.26	S-06/0-4 ft bgs
Nickel	13 or SB	15	46.1	S-02/0-4 ft bgs
Selenium	2 or SB	2	5.46	S-06/0-4 ft bgs
Zinc	20 or SB	31	495	S-03/4-8 ft bgs

With the exception of three samples (S-02 8 to 12 ft bgs, S-03/12 to 16 ft bgs, and S-04/12-16 ft bgs), at least 4 metals were detected in each sample with concentrations exceeding the cleanup objectives. The sample with the most exceedances (10 was collected at the S-06 from 0 to 4 feet

bgs. Typically, the samples collected from the near surface interval (0 to 4 feet bgs) had the most exceedances which is not uncommon for an urban setting.

4.2 GROUNDWATER

The results of the groundwater samples collected from the monitoring wells (Table 3) show that VOCs were either not detected or detected in concentrations below the NYSDEC Class GA groundwater standards in the samples collected at MW-1, MW-2, and MW-3. However, at MW-4, several VOCs were detected including 13 compounds with concentrations exceeding the NYSDEC Class GA groundwater standards. These compounds included vinyl chloride (2.1 µg/l), chloroethane (11.4 µg/l), acetone (958 µg/l), methylene chloride (10.4 µg/l), 1,1-dichloroethane (18.8 µg/l), c-1,2-dichloroethene (14.9 µg/l), 2-butanone (52.9 µg/l), benzene (32 µg/l), toluene (17,800 µg/l), ethylbenzene (3,620 µg/l), total xylenes(18,910 µg/l), isopropylbenzene (9.1 µg/l), and 1,2,4-trimethylbenzene (12.6 µg/l). The total VOC concentration at MW-4 was 41.7 mg/l. A duplicate sample, identified as MW-5, detected similar concentrations. MW-4 is the closest downgradient monitoring well to the asphalt parking lot at the Kent Street portion of the site.

The SVOC results of these samples showed total detected concentrations ranging from 2.16 µg/l at MW-3 to 61.2 µg/l at MW-4. No SVOC concentrations exceeded the Class GA groundwater standards. Only six (6) SVOCs were detected and no more than three (3) were detected in any groundwater sample. No pesticides or PCBs were detected in these samples. Metals that were detected in concentrations exceeding their respective groundwater standards include arsenic, iron, lead, magnesium, manganese, sodium, and thallium. The iron, manganese, sodium, and thallium (where detected) concentrations exceeded the Class GA standards in each of the samples and are likely indicative of the regional groundwater quality rather than resulting from site impacts. As expected, the results of the filtered sample were generally less than the concentrations of the unfiltered sample. Arsenic (30 µg/l) at both MW-1 and MW-4 and lead (87 µg/l) at MW-3 were detected at concentrations exceeding the Class GA standards (both 25 µg/l) in the filtered sample but below the standards in the unfiltered sample. No potential sources of either metal were identified near either monitoring well.

Results of the groundwater samples collected from the soil borings (Table 4) advanced during this investigation are generally consistent with the soil samples collected at the same location. Samples W-01, W-02, and W-04 had elevated BTEX concentrations, consistent with the soil samples. The total BTEX concentrations detected in groundwater at these borings is 7.44 mg/l, 35.2 mg/l, and 8.11 mg/l, respectively. These results are also consistent with previous samples collected by others although at lower concentrations. No other VOCs were detected in sample W-01. Seven other VOCs were detected at concentrations exceeding the Class GA standards including 1,2-DCA (10 µg/l) and PCE (11.2 µg/l) from the W-02 sample. At W-04, acetone

(2,100 µg/l) and methylene chloride (20.5 µg/l) were also detected at concentrations exceeding the Class GA standards. Only naphthalene (3.1 µg/l) was detected in the sample collected at S-06, and this concentration was below its standard. No VOCs were detected in the groundwater sample collected at W-08. S-06 and W-08 represent groundwater conditions at the former Pfizer property.

No SVOCs were detected at concentrations exceeding the standards in the groundwater samples collected from the borings at this site. The total detected SVOC concentrations ranged from 0.51 µg/l at W-01 to 6.95 µg/l at S-06. In addition, no pesticides or PCBs were detected in these samples.

The results of the metals analyses of the groundwater samples collected from borings are generally consistent with the results of samples collected from the monitoring wells. Concentrations of iron, manganese, sodium, and thallium (where detected) were above the standards in both the filtered and unfiltered samples at each boring. These results are further indication of the regional groundwater quality. As expected, the filtered sample results were less than the unfiltered sample results. Ten metals were detected in concentrations that exceeded the standards in the unfiltered analyses but were below the standards in the filtered analyses. The only exceptions were the antimony and selenium concentrations detected at S-06 and the magnesium concentrations detected at W-01, W-02, and S-06. The antimony concentrations for the unfiltered and filtered samples at S-06 were 28 and 9 µg/l, respectively. For selenium, the respective concentrations were 42 and 28 µg/l. Unfiltered magnesium concentrations for samples W-01, W-02, and S-06 were 139, 92.5, and 503 mg/l whereas the filtered concentrations were 82.8, 75.2, and 563 mg/l, respectively. The groundwater sample collected at S-06 had the most exceedances (14) of the metal standards in the filtered sample. For the filtered analyses, the W-01, W-02, and S-06 samples each had five metals with concentrations exceeding the class GA standards. Boring S-06 was advanced near the southwest corner of the Pfizer property with the objective of assessing the historic fill.

4.3 SEDIMENT

Results of both the manhole (M-01) and storm drain (D-01) samples (Table 5) show essentially little or no VOC, pesticide and PCBs impact. However, several SVOCs were detected including six (6) with concentrations exceeding the soil cleanup objectives.

Methylene chloride was detected in both the M-01 (0.0177 mg/kg) and D-01 (0.0084 mg/kg) samples. Methyl ethyl ketone (0.0019 mg/kg) was detected in the M-01 sample but not in the D-01 sample. No other VOCs were reported in concentrations above the method detection limits. Similarly, no pesticides were reported above the detection limits. Only one PCB, Aroclor 1260,

SB - Site background.
Note: - Numbers in bold exceed cleanup objective.
NR - Compound not analyzed.

was detected in both the M-01 (0.612 mg/kg) and D-01 (0.039 mg/kg) samples. All VOCs, pesticides, and PCB concentrations were below the soil cleanup objectives.

The six (6) SVOCs that were detected in concentrations above the soil cleanup objectives in both the M-01 and D-01 samples include benzo(a)anthracene (1.94 and 3.28 mg/kg), chrysene (2.11 and 4.03 mg/kg), benzo(b)fluoranthene (1.87 and 3.45 mg/kg), benzo(k)fluoranthene (1.89 and 3.27 mg/kg), benzo(a)pyrene (1.72 and 3.24 mg/kg), and dibenzo(a,h)anthracene (0.349 and 0.895 mg/kg) respectively. The total detected SVOC concentrations were 27.5 and 54.4 mg/kg, respectively. TPH results of the two samples are 356 mg/kg and 520 mg/kg, respectively.

Eleven metals were detected in concentrations exceeding the soil cleanup objectives. These metals include arsenic, barium, beryllium, cadmium, chromium, copper, iron, mercury, nickel, selenium, and zinc. With the exception of the copper concentration in the storm drain sample and the mercury and zinc concentrations in both samples, the exceedances were generally an order of magnitude or less. The copper concentration detected in the storm drain sample was 2,080 mg/kg, above the cleanup objective of 25 mg/kg. Mercury concentrations detected in the manhole and storm drain samples were 32.3 and 23.2 mg/kg, respectively, above the cleanup objective of 0.1 mg/kg. Zinc concentrations were 1,250 mg/kg and 1,750 mg/kg, respectively, above the cleanup objective of 20 mg/kg. These samples were also submitted for TCLP metals analyses with the results indicating no exceedances of the maximum concentrations for toxicity characterization.

4.4 SUMMARY

BTEX constituents were detected above cleanup objectives/standards in both soil and groundwater samples collected from borings advanced in the asphalt parking area adjacent to Kent Avenue. These results confirm previous results of a liquid sample collected in this area by others. The highest concentrations detected in both the soil and groundwater were from samples collected at boring S-02, which is adjacent to the neighboring building to the south. The concentration levels detected in these samples and the previous liquid sample are higher than what would be expected from the No. 6 fuel oil that is stored in the Con Edison 10,000 gallon UST that is in this area. In addition, the UST has consistently past tank tightness testing, according to Con Edison personnel and Con Edison's records. Therefore, the source of these constituents are believed to originate from an off site source, likely the adjacent property to the south.

BTEX constituents were also detected in a soil sample collected from the S-09 boring that was advanced near the northeast portion of the former Pfizer property. Because this area is downgradient of the asphalt parking area, the source of these constituents is likely from the same source as described above. A second potential source is a suspected 550 gallon UST that may

have existed at the northern portion of the site according to the December 1992 Phase I ESA Report (H2M, 1992). However, the UST area was not identified and the geophysical survey indicated that a UST could not be located.

The BTEX constituents were also detected in a groundwater sample collected from the existing MW-4 located in the sidewalk adjacent to River Street, approximately halfway between Metropolitan Avenue and North First Street. The well was installed to serve as an upgradient well for the fuel oil storage tanks. The total detected VOC concentration detected in a sample collected from this well was 41.7 mg/l, higher than the results of samples collected adjacent to the fuel oil tank. This results suggests that the BTEX constituents are migrating and the extent of the migration may now be beneath the oil storage tanks. If the BTEX constituents detected at each area originate from the same source, the extent of the BTEX impacted area is at least 70 feet long and 100 feet wide, conservatively, which is the approximate distances from the eastern property limit to MW-4 and from soil boring S-09 to MW-4, respectively. The impacted area likely extends beyond these areas.

SVOCs were detected in concentrations above the cleanup objectives at four of the five borings advanced on the former Pfizer property. These concentrations are generally an order of magnitude or less above the cleanup objectives. Results of groundwater samples collected from two borings (S-06 and S-08) advanced on the former Pfizer property indicate that there is little or no SVOC impact to the groundwater. SVOC cleanup objective exceedances were also detected in samples collected at borings S-10 and S-12. These borings were advanced adjacent to the oil storage tanks. No source of the SVOC constituents was identified in the previous site related documents or during the field activities.

No pesticides were detected in any sample collected at the site during this investigation. PCBs were detected in eight (8) soil samples, but at concentrations below the cleanup objective. PCBs and pesticides were not detected in any groundwater samples collected at the site during this investigation.

Metal concentrations detected in the soil are consistent with concentrations normally detected in urban fill. The metal concentrations detected in the groundwater samples are likely indicative of the regional quality. Following filtration, the metal concentrations decreased as expected. Therefore, the metal concentration exceedances detected in the unfiltered groundwater samples are likely attached to colloidal particles suspended in the groundwater.

The results of the manhole and storm drain sediment samples suggest some impact from the site activity has occurred at these areas. No VOCs exceeded the cleanup objectives in either sample, but concentrations of 6 SVOCs exceeded the objectives. No pesticides or PCBs exceeded the cleanup objectives in either sample. In both samples, eleven metals were detected in

concentrations above the objectives. In general, the SVOC and metal exceedances were an order of magnitude or less above their respective cleanup objectives.

At present, Con Edison is accepting bids on the subject site as part of their divestiture plan in accordance with the Public Service Commission's (PSC) requirement to liquidate properties for the potential future use as a power generation sites. However, it is unclear at this time whether the site will actually be used for this purpose, commercial or residential.

5. CONCEPTUAL REMEDIAL ALTERNATIVES

The purpose of this section is to identify and assess potential remedial alternatives that may be considered for the North First Street site. The Phase I Investigation (September 1999), historical data and the Phase II investigation conducted in November/December 1999 were used identify the areas of concern that may require some level of remediation. The remedial approach described herein was developed based on the limited data available and various assumptions regarding subsurface constraints, groundwater flow and the nature and extent of contamination.

5.1 GROUNDWATER IMPACTS

A 10,000 gallon underground storage tank (UST) formerly used for fuel storage is located on the site between River Street and Kent Avenue. Historically, there has been no evidence of a fuel leak, however, high concentrations of xylenes and toluene were detected in a boring (1996) advanced during the installation of cathodic protection. Xylene and toluene contamination was detected at levels exceeding 50% – 60%, indicative of pure product. These concentration levels are not typically associated with fuel oils; therefore, the source of the contamination most likely originates from an off-site facility. As discussed in the previous chapter of this report, groundwater data was collected from the four existing monitoring wells on-site. The data revealed fairly high concentrations of VOCs in the eastern most well (MW-4) presumed to be from the same source detected in 1996 around the 10,000-gallon fuel tank.

The historical data in conjunction with the recent data collected in 1999 reveals that the site groundwater is impacted by VOCs and some level of remediation would likely be required. The source for the contamination is unknown but presumed to be an adjacent property owner to the Con Edison facility. Based on this information, it appears that additional investigation is required to better delineate the source and extent of the groundwater contamination. For the purposes of this report, various assumptions were made regarding the extent of contamination in order to formulate a conceptual remedial action plan.

5.2 SOIL AND SEDIMENT IMPACTS

The site property located to the south, known as the former "Pfizer site" includes two molasses storage tanks and a sulfuric acid tank (reportedly cleaned). Historical remediation in this area includes soil excavation and disposal, however, borings gathered in December 1999 reveal that the site soils in this area exceed recommended soil cleanup objectives for various semi-volatile organic compounds and metals. The semi-volatile compounds detected suggest the contamination is due to fuel oil number 4, 5, or 6, or lubricating oils. Metals detected in exceedance of recommended clean-up levels include arsenic, mercury, copper, nickel and zinc. High levels of iron were also detected but may be indicative of the site background iron levels.

Sediment samples collected from drain penetrations and a manhole at the former Pfizer site also reveal the presence of semi-volatile organic compounds and metals in exceedance of recommended soil cleanup objectives. In general, the same compounds detected in the soils were also detected in the drain and manhole; however, the mercury, copper and nickel concentrations detected were ten to thirty times greater than the concentrations detected in the soil borings. Remedial action in the form of hot spot soil excavation and disposal is likely to be required in this area, however, the data is fairly weak and better delineation would be required to delineate areas of concern and boundaries of excavation. Various assumptions were made in developing the conceptual remedial approach described in this section.

Historical information revealed that a 550 gallon UST was possibly located in the northern portion of the former Pfizer site. Data collected in that area revealed that a UST does not currently exist in this area. However, the boring advanced near the northeast corner of the former Pfizer property shows that some BTEX constituents were detected at concentrations exceeding cleanup objectives. As discussed above in the groundwater impacts section, further investigation to delineate the extent of the BTEX constituents is required for this area.

5.3 MISCELLANEOUS ITEMS

There is historical evidence that a mycelium and sulfuric acid heating coil may have been disposed on site. The data gathered in December 1999 revealed that some SVOCs and metals were detected at concentrations exceeding the cleanup objectives in this area. Remedial action encompassing limited hot spot soil excavation in the former Pfizer site may be required for this area.

Miscellaneous containers of toxic or hazardous materials should be properly disposed of off-site. This includes a lead containment tub located in the building on the former Pfizer site. The six (6) fuel oil storage tanks should be cleaned and closed in accordance with applicable procedures. These tanks are reportedly removed from service and certified gas free in accordance with

applicable bulk storage regulations. The 234 gallon AST that stored fuel for the emergency backup generator and the 3,000 gallon AST used to store foamite for fire suppression should be cleaned and properly closed in accordance with applicable procedures if not intended for use by the prospective future owners.

5.4 CONCEPTUAL REMEDIAL ACTION

Of the impacts listed above, the groundwater condition seems to require the most attention due to the concentrations of volatiles detected in the shallow groundwater which exceed 40 parts per million of total volatile organic compounds (VOCs) criterion of New York Department of Environmental Conservation (NYSDEC). Although the groundwater use in the immediate area is limited and the classification of the directly impacted surface waters (East River) is not as restrictive as other water bodies, it is expected that additional investigation will be required to identify and stop the source of the VOC contamination prior to considering a groundwater remedial alternative. However, it is likely that some form of groundwater remediation may be required by NYSDEC in the future. However, the responsible party can not be determined based on the current investigation. Therefore, the following clean up alternatives are presented only as possible scenarios. Con Edison may not be responsible party and any groundwater remediation may be responsibility of other(s). In general, the major remedial action goal for the site is to prevent human exposure (inhalation, ingestion, and dermal contact) to the VOC contaminants in the shallow, on-site groundwater. A secondary remedial action goal is to limit further off-site migration of the shallow groundwater contamination. The specific remedial action objectives for the groundwater may be established by the NYSDEC groundwater standards. Achievement of these objectives is believed to be protective of human health and the environment.

A wide array of alternatives exists for groundwater remediation. These alternatives range from a no action alternative/natural attenuation to active pump and treat applications. The objective of this remedial action conceptual plan is to propose remedial activities that would address and remediate contaminated groundwater at the site, identify potential treatment and containment technologies that will satisfy the objectives and screen the technologies to eliminate those that cannot be implemented technically at the site.

Pump and treat alternatives have been screened out of this conceptual plan due to the usually high costs, required footprints and remediation life cycle costs. In addition, chemical remediation, bioremediation and biowalls are not discussed although, pending NYSDEC approval, could be considered viable alternatives to the options presented herein if long-term remediation were acceptable to the parties involved. If agreeable to the goals of Con Edison and NYSDEC, and depending upon the required remediation schedule, further investigation into these technologies is warranted.

Remedial alternatives are developed and then evaluated considering various criteria. These evaluation criteria generally are (1) protection of human health and the environment, (2) compliance with recommended guideline values, (3) reduction of toxicity, mobility, and volume, (4) short term effectiveness, (5) long term effectiveness and permanence, (6) implementability, and (7) cost. These seven criteria serve as the basis for conducting detailed analyses and for subsequently selecting an appropriate remedial action. The process of alternative development, screening, and evaluation is done in context with remedial action objectives developed for the site and the quantities of contaminated materials found to present based on the data gathered. The eighth and ninth criteria, community and state acceptance, are also to be considered in evaluating the remedial alternatives

Based on the data available and other project issues such as available time frames to perform remediation, site conditions and subsurface constraints the traditional approach has been streamlined to better reflect the actual project requirements.

5.5 REMEDIAL ACTION OBJECTIVES

Remedial action objectives are developed for a site to determine the levels to which contaminant concentrations must be reduced to protect human health and the environment. For the purposes of this study, the recommended soil cleanup objectives and Class GA groundwater standards will be considered. It is important to note that groundwater class GA standards are one of the more restrictive classifications and the actual remedial goals (established by the NYSDEC) should be less restrictive than the class GA requirements.

5.6 QUANTITIES OF CONTAMINATED MEDIA

The remedial action objectives discussed in the previous section were used to estimate the quantities of contaminated media present at the North First Street site. The estimated quantities of contaminated shallow groundwater are used to evaluate potential remedial alternatives for the site. The quantity of contaminated shallow groundwater of concern for the North First Street site is estimated to be 2.4 million gallons which assumes a 62,500 square feet of impact area to a depth of 25 feet and a soil porosity of 20%, but does not include groundwater migration into and out of the contaminated area.

The quantity of contaminated soils and sediment for the North First Street site is estimated to be 500 cubic yards (CY); or a total area encompassing 2,500 square feet to depths of about 5 feet. This estimate is preliminary and assumes hot spot excavations including drain and manhole refurbishment and closure.

Remedial alternatives are developed and then evaluated considering various criteria. These evaluation criteria generally are (1) protection of human health and the environment, (2) compliance with recommended guideline values, (3) reduction of toxicity, mobility, and volume, (4) short term effectiveness, (5) long term effectiveness and permanence, (6) implementability, and (7) cost. These seven criteria serve as the basis for conducting detailed analyses and for subsequently selecting an appropriate remedial action. The process of alternative development, screening, and evaluation is done in context with remedial action objectives developed for the site and the quantities of contaminated materials found to present based on the data gathered. The eighth and ninth criteria, community and state acceptance, are also to be considered in evaluating the remedial alternatives

Based on the data available and other project issues such as available time frames to perform remediation, site conditions and subsurface constraints the traditional approach has been streamlined to better reflect the actual project requirements.

5.5 REMEDIAL ACTION OBJECTIVES

Remedial action objectives are developed for a site to determine the levels to which contaminant concentrations must be reduced to protect human health and the environment. For the purposes of this study, the recommended soil cleanup objectives and Class GA groundwater standards will be considered. It is important to note that groundwater class GA standards are one of the more restrictive classifications and the actual remedial goals (established by the NYSDEC) should be less restrictive than the class GA requirements.

5.6 QUANTITIES OF CONTAMINATED MEDIA

The remedial action objectives discussed in the previous section were used to estimate the quantities of contaminated media present at the North First Street site. The estimated quantities of contaminated shallow groundwater are used to evaluate potential remedial alternatives for the site. The quantity of contaminated shallow groundwater of concern for the North First Street site is estimated to be 2.4 million gallons which assumes a 62,500 square feet of impact area to a depth of 25 feet and a soil porosity of 20%, but does not include groundwater migration into and out of the contaminated area.

The quantity of contaminated soils and sediment for the North First Street site is estimated to be 500 cubic yards (CY); or a total area encompassing 2,500 square feet to depths of about 5 feet. This estimate is preliminary and assumes hot spot excavations including drain and manhole refurbishment and closure.

Alternative 1 for Groundwater remediation is Air Sparging/Soil Vapor Extraction/Vapor Treatment. This alternative considers the installation of an air sparging/soil vapor extraction (AS/SVE) system to remediate the shallow groundwater contamination at the site. Off-gas treatment and long-term groundwater monitoring are also implemented as part of this alternative. There are several reported advantages of using the air sparging technology over other methods for remediating contaminated groundwater including:

- Cost savings because there is no need to pump, handle, and treat groundwater at the surface; only contaminated vapor is extracted and treated in this technology.
- Integration with other remediation techniques.
- Flexibility of design.
- Successful implementation at numerous sites.

Some limitations reported for this technology include:

- Some constituents (such as metal compounds) may form complexes with the soil matrix, which may decrease volatilization rates.
- Heterogeneous soils may cause channeling (the preferential movement of air though high conductivity layers), thus limiting the effectiveness of the treatment.
- Aquifer clogging may occur when increased iron precipitation or biomass accumulation caused by oxygen injection changes subsurface characteristics.
- Soils in the unsaturated zone may become incidentally contaminated during the extraction of contaminated vapors.
- Extra planning and design may be warranted to attain sufficient air delivery to the saturated zone while preventing undesirable effects such as vapor migration and groundwater mounding.
- Subsurface constraints such as underground utilities, building foundations and fill materials may interfere with the construction and/or effectiveness of the remediation;
- Generally, the technology can not effectively remediate the areas under the existing fuel storage tanks; specifically tank "B: complex" where the plume may conceptually lie; groundwater flow patterns are generally unknown without groundwater elevation data. The primary concern is the flow pattern under the tank complex.
- Due the shallowness of the groundwater and the potentially large surface area that must addressed, vertical SVE wells may be numerous and costly. Likewise, horizontal SVE wells, which are better suited for shallow vadose zones, may be limited due to construction constraints (i.e. streets of New York City) and limited by access.

Air sparging/soil vapor extraction is a demonstrated in-situ physical/chemical treatment alternative for remediating contaminated groundwater, as per EPA's Superfund Innovative Technology Evaluation (SITE) program. Air sparging is an in-situ technology employed to

volatilize contaminants from the groundwater to the unsaturated zone. SVE then removes the volatilized contamination from the unsaturated zone to the ground surface, typically for vapor-phase treatment.

In AS/SVE technology, compressed air is injected into air sparge wells at controlled pressures and volumes to introduce air channels into the contaminated saturated zone. The channels induce in-situ air stripping of dissolved VOCs and volatilize trapped and adsorbed phase contamination present in the aquifer. In addition, aerobic biodegradation of the contaminants may also occur, depending on site-specific conditions. The channels containing contaminants travel from the saturated zone up to the unsaturated zone. The injection sparge wells are arranged such that the entire area requiring treatment is effectively aerated, which may involve creating overlapping zones of influence.

An SVE system then collects vapor-phase VOCs and transports them to the surface for subsequent treatment. The SVE system consists of vapor extraction points (VEPs) placed in the unsaturated zone above the contaminated groundwater and a vacuum system at the ground surface to remove vapors from the VEPs.

Unlike conventional groundwater remediation systems, air sparging does not require groundwater to be pumped to and treated at the surface. The technology is most applicable to VOCs, SVOCs, and non-volatile aerobically biodegradable organic contaminants. Air sparging has been used at sites with high yield aquifers and relatively course-grained (moderate to high permeability) homogeneous material that provides an effective contact between air and the contaminated medium being treated. The subsurface conditions at the North First Street site are not ideal for SVE due to the soils type (and typical permeability). However, successful SVE systems have been instituted in applications with similar subsurface conditions and the paved surfaces typical for that area will greatly reduce short-circuiting of soil vapors. It is strongly recommended that a pilot test be performed prior to any final design.

Air compressors or blowers are typically used to deliver a stream of air under pressure to the subsurface via the sparging wells, and vacuum pumps are utilized for the removal of contaminants in the vapor phase. The aboveground AS/SVE system components also typically include a vapor treatment system and a process control system to monitor and adjust air delivery and removal equipment for maximum remediation efficiency.

For the purposes of this report, a preliminary assessment of the AS/SVE system configuration, radii of influence, and air flow rates has been made based on historical application and reported subsurface conditions. At the North First Street site, the air sparging system would include the installation of approximately six air injection sparging wells, each consisting of 2-in diameter Schedule 40 PVC, to address the shallow groundwater contamination plume. The number of

sparging wells was derived based on a total plume area of approximately 62,500 SF and radii of influence of approximately 25 ft in each sparge well. Figure 2 shows approximate locations of the air injection wells. Each well will be mounted flush with the existing ground surface and installed to approximate depths of 15 - 25 ft bgs. A 15-hp air compressor unit should be capable of producing a free flow rate of approximately 60 scfm (approximately 10 scfm per injection point). The conceptual plans shows the air sparging wells forming a curtain of treatment in what is assumed to be the center of the plume area. This approach is necessary since active air sparging under the tank fields where the plume may lie, is not viable unless the tanks were demolished. Pilot testing and field measurements in the design phase of the work will more accurately determine the exact number and placement of each of the air sparging wells, along with specific subsurface air distribution patterns expected to result.

Approximately 6 – 8 vapor extraction points (VEPs) are estimated to be necessary to address the removal of VOCs transported though the unsaturated zone. Depending on the nature of the site soils this number may double specifically if the soils are heterogeneous with varying degrees of permeability. The installation of shallow SVE trenches can also be considered as an alternative to vapor extraction wells. The trenches are advantageous in that they can cover a larger surface area when compared to a well; however, the construction of these trenches in the streets of New York City may be difficult. Pilot testing and field measurements in the design phase of the work will determine the exact number, placement, and depth of each of the VEPs. Each well will be mounted flush with the existing ground surface and installed within the unsaturated zone. Each VEP will be 2 inches in diameter, and constructed of Schedule 40 PVC. A vacuum blower (approximately 10 hp) with a flow rate of approximately 120 –160 scfm would be used for the SVE system.

Components of the air sparging/SVE system include air compressor blower(s), inlet filter(s), and associated piping; a vacuum blower(s), filter(s), associated piping, and moisture separator; vapor-phase granulated activated carbon (GAC) units (described below); piping; system control equipment (i.e., valves, meters, electronics, gauges, etc.); and a structure to house system components and vapor treatment equipment. A part-time operator will be needed to operate and supervise the AS/SVE process and treatment plant.

Operation and maintenance costs include electricity to operate the system; periodic repair and replacement of system parts/components; routine operator inspection of the system; and system monitoring. System inspection and monitoring activities consist of routine visits to the site to inspect the air sparging and SVE components and collect real-time air measurements, as necessary.

Prior to final design, a pilot-scale treatability study will be performed to determine the overall effectiveness of the AS/SVE technology along with configurations (aerial locations and depths)

Pearl River, New York

of sparging wells, VEPs, and system piping at the site. Site-specific design parameters, such as zones of air distribution, injection air pressures, injection flow rates, and mass removal efficiency, can be obtained from a pilot test. A pilot scale test can also evaluate vapor phase treatment approaches. In addition, the extent of channeling at the site can be evaluated. The results of the pilot test will also be used to better estimate the run time and power requirements of the system.

It is assumed that the remedial objectives for the shallow groundwater contaminant plume at the North First Street site will be met in three – five years. The actual cleanup time may be longer than three – five years; better estimates of cleanup time can be made based on the pilot-scale treatability study. Remedial objectives are considered to be achieved when all compliance monitoring results meet specified criteria in two consecutive sampling episodes.

VOCs in the vapor phase are collected from each VEP and pumped with a vacuum extraction blower to a vapor treatment system. The overall vapor phase flow rate for the shallow contaminant plume is expected to be approximately 120 - 160 scfm. Most likely in New York City air emissions will require treatment by granular activated carbon (GAC). A preliminary review of the VOC constituents and respective vapor phase concentrations indicates that an emission stack will probably be required as well. However, the ultimate configuration of the entire vapor recovery/treatment system, including should be based on the results from the pilot study. Air monitoring and inspection of the vapor treatment system after startup may also determine system requirements.

The concentration of total VOCs in the groundwater exceeds 40 ppm. Although the exact partitioning rates from the air to water, and the soil to gas partitioning is unknown without pilot test data, it would appear vapor treatment will be required for this site. The primary constituents such as toluene and xylene are generally amiable to GAC adsorption, however, the others, such as vinyl chloride, are not. GAC was the assumed vapor phase treatment option for the air sparging/SVE alternative. However, other vapor phase treatment options (i.e., catalytic oxidation and UV treatment) should be evaluated during the final design and treatability study.

To confirm that the AS/SVE system is achieving remedial objectives, groundwater samples will be collected from piezometers installed for system performance monitoring and analyzed for VOCs. The results of these analyses will be used to determine whether remedial action objectives are being satisfied, and whether changes in system design, configuration, and operation are required. Long-term groundwater monitoring will be conducted on a periodic basis to determine if remedial objectives are being met. It is assumed that groundwater monitoring will be conducted twice per year for five years beyond remediation system startup.

The continued need for monitoring can be re-evaluated and possibly discontinued at any time during the 5-yr period. For example, if groundwater contaminant levels remain below the site

remedial action objectives for two consecutive sampling events, the monitoring program may be discontinued. If contaminant levels continue to exceed the remedial action objectives at the end of the 5-yr period, the monitoring program and system operation will be extended and/or other remedial actions may be taken.

Alternative 2 for groundwater treatment is In-Well Vapor Stripping/Vapor Treatment. This alternative includes remediating the shallow, on-site groundwater at the North First Street site by implementing in-well vapor stripping, an in-situ remediation technology, and off-gas treatment. This alternative also includes long-term monitoring of the groundwater plume. The reported advantages of using the in-well vapor stripping technology over other methods for remediating contaminated groundwater include:

- Cost savings because there is no need to pump, handle, and treat groundwater at the surface; only contaminated vapor is extracted and treated in this technology.
- System can be designed so that soils in the unsaturated zone do not become incidentally or temporarily contaminated during groundwater remediation.
- Simplicity of design.
- Limited maintenance requirements.

Some limitations reported for this technology include:

- Possible clogging of well screens due to precipitation of iron or other nutrients present in the subsurface.
- Potential to spread contaminants in the subsurface if the system is not properly designed or constructed.
- Lower effectiveness in shallow aquifers (due to limited area for groundwater recirculation).
- Subsurface constraints such as underground utilities, building foundations and fill materials may interfere with the construction and/or effectiveness of the remediation;
- Generally, can not effectively remediate the areas under the existing fuel storage tanks; specifically tank "B: complex where the plume may conceptually lie; groundwater flow patterns are generally unknown without groundwater elevation data. The primary concern is the flow pattern under the tank complex.

Several commercial variations of the in-well vapor stripping process have been developed. Three main types of in-well vapor stripping systems include the Unterdruck-Verdampfer-Brunnen (UVB) or "vacuum vaporizer well" system, the NoVOCs™ system, and the Density Driven Convection (DDC) system. The UVB in-well vapor stripping system was selected for analysis because of several reasons:

- The large amount of information and research readily available in the literature.

- Flexibility of the system to operate under various site conditions.
- Decreased moisture content in vapors to be treated.
- Lower likelihood of well screens to become clogged by iron precipitates.
- Previous demonstration at sites with other physical and contaminant characteristics similar to the North First Street site..

In-well vapor stripping (also known as in-situ vacuum, vapor, or air stripping) is a demonstrated in-situ physical/chemical treatment alternative for remediating contaminated groundwater, as per EPA's Superfund Innovative Technology Evaluation (SITE) program. The technology involves the creation of groundwater circulation patterns, or "cells", in the subsurface surrounding specially designed wells and simultaneous aeration within the wells to volatilize VOCs from the circulating groundwater. Contaminated vapors are typically extracted from the wells and treated at the surface; however, unlike conventional groundwater remediation systems, in-well vapor stripping does not require groundwater to be pumped to and treated at the surface. This in-well air stripping technology is most applicable to VOCs. However, modifications of the basic remedial process are proposed for applications to treat SVOCs, pesticides, and inorganics. In-well vapor stripping has been used in unconfined and confined aquifers and applied to geologic materials with a range of characteristics.

An in-well stripping well consists of an inner and an outer casing that are hydraulically separated from one another, usually by a packer or divider plate. This separation ensures one-directional flow of groundwater into the well at its base (through a lower screened interval) and out of the well near the water table (through an upper screened interval). Air is injected into the well through a gas injection line and diffuser, releasing bubbles into contaminated groundwater in the well. These bubbles aerate the water and form a type of air-lift pumping system (due to an imparted density gradient) that causes groundwater to flow upward in the well. As the bubbles rise, VOC compounds in the water are transferred from the dissolved state to the vapor state through an air stripping process.

The air/water mixture rises in the well until it encounters the dividing device within the inner casing. The divider is designed and located within the well to maximize volatilization. The air/water mixture flows from the inner casing to the outer casing through the upper screen. A vacuum is applied in the outer casing, and contaminated vapors are drawn upward through the annular space between the two casings and typically treated at the ground surface. The partially treated groundwater, from which some of the VOCs have been removed, re-enters the subsurface through the upper screen and infiltrates back to the aquifer and the zone of contamination where it is eventually cycled back into the well. This pattern of groundwater movement forms a circulation cell in the subsurface around the well that allows groundwater to undergo sequential treatment cycles until remedial objectives are achieved. The treated water may also be diverted to a re-injection gallery upgradient of the in-well stripping to flush out the system. A continuous

organic-rich vapor stream is created as contaminant concentrations in groundwater are significantly reduced.

At the North First Street site, the in-well vapor stripping system would include the installation of three – four groundwater circulation/stripping wells (8-in. diameter) to address the shallow, on-site groundwater contamination plume based on contaminant depths and radii of influence expected to be achieved (Figure 3). Each well will be mounted flush with the existing ground surface and installed to approximate depths of 25 ft bgs. The estimated groundwater flow rate in each well is 10 - 50 gallons per minute (gpm). Aquifer pump testing and field measurements in the design phase of the work will more accurately determine the construction details and placement of each of the in-well vapor stripping wells, along with specific groundwater circulation/treatment patterns expected to result.

Components of the in-well vapor stripping system include: air injection blowers and associated piping; vacuum extraction blowers (for vapor collection) and associated piping; a moisture separator and condensate storage container; system control equipment (i.e., valves, meters, electronics, gauges, etc.); an iron sequestering/pH control system; and a structure to house system components and vapor treatment equipment. A part-time operator will be needed to operate and supervise the in-well vapor stripping process and treatment plant.

Operation and maintenance costs include electricity to operate the system; periodic repair and replacement of system parts/components; iron control chemical replenishment; routine operator inspection and maintenance of the system; and system monitoring. System inspection, maintenance, and monitoring activities consist of routine visits to the site to inspect and clean the in-well vapor stripping components and collect real-time air measurements, as necessary.

Prior to final design, a pilot-scale treatability study and aquifer pump test will be performed to determine the overall effectiveness of the in-well vapor stripping technology and well/piping configurations at the site. A pilot scale test can also determine optimal operating pressures and flow rates to remove contaminants from the groundwater and evaluate the airflow distribution and vapor phase treatment approaches. In addition, control of iron and pH in the subsurface can be evaluated. The results of the pilot test will also be used to better estimate the run time and power requirements of the system.

To confirm that the in-well vapor stripping system is achieving remedial objectives, periodic groundwater sampling will be conducted. It is assumed that groundwater samples would be collected from existing monitoring wells at the site and analyzed for VOCs. The results of these analyses will be used to determine whether remedial action objectives are being satisfied, and whether changes in system design, configuration, and operation are required. Groundwater monitoring is assumed to be conducted twice per year for five years beyond remediation system

startup. The continued need for monitoring can be re-evaluated and possibly discontinued at any time during the 5-yr period. For instance, if groundwater contaminant levels remain below the site remedial action objectives for two consecutive sampling events, the monitoring program may be discontinued. If contaminant levels continue to exceed the remedial action objectives at the end of the 5-yr period, the monitoring program, and system operation, will be extended and/or other remedial actions may be taken.

5.7 HOT SPOT EXCAVATION AND DISPOSAL

Based on the soil data gathered in December 1999, it appears that some areas (Figures 2 and 3) will likely require hot spot soil excavations and disposal of hazardous or non hazardous soils. This remedial approach is readily implementable and advantageous since it eliminates the source of contamination and reduces long-term liabilities and monitoring requirements. For the purposes of this estimate, it is assumed that 500 CY of various soils require disposal to depths no greater than 5 feet. This includes the soils and sediment associated with the Pfizer site drains and manholes.

It was further assumed that the excavations would have to hand excavated to depths of 4 feet to avoid subsurface utilities. The collected soils would be staged on site, sampled and properly disposed of in accordance with applicable requirements. For the purposes of this estimate, it is assumed that 80% of soils would be non-hazardous and 20% would classified as hazardous wastes.

Subsequent to the hot spot excavation, this approach assumes that end point sampling would be required to ensure that the soils were remediated to maximum extent possible.

1. OBJECTIVE

This work plan as part of the Phase II environmental site assessment (ESA) investigation for the North First Street Oil Storage Terminal Site has been formulated after reviewing the Phase I documents and other site documentation provided by Con Edison. Documentation that was formulated to identify recognized environmental conditions on the site, generally as that term has been defined by ASTM was reviewed. The next stage of the process is to perform site sampling to confirm or refute any significant contamination on the site relative to regulatory standards and guidelines. The scope is designed to characterize contamination. If impacted areas are identified, additional samples may be collected to delineate such conditions, if possible.

The North First Street Oil Storage Terminal site is bordered by North 3rd Street to the north, the East River to the west, Grand Street Park and Grand Street to the south, and River Street to the east. A portion of the site is bounded by Metropolitan Avenue to the north, River Street to the west, Kent Avenue to the east, and an adjoining warehouse property to the south. The site consists of two areas containing large, above ground, oil storage tanks, the former Pfizer property to the south, and a building containing offices, a boiler room, and control room with an adjacent parking lot to the east. The former Pfizer property was previously used for transfer and storage of molasses and sulfuric acid for cough syrup production. Based on the site's proximity to the East River, groundwater is expected to flow westward.

2. BACKGROUND

A Phase I ESA report, dated 10 September 1999, was prepared by Holzmacher, McLendon, and Murrell, P.C. (H2M). The Phase I report identified a number of recognized environmental conditions at the site:

- There is a suspected 550 gallon underground storage tank at the northern portion of the Pfizer property and a 2,000 gallon UST near the southeast corner of the Pfizer property that lack appropriate closure documents and may constitute recognized environmental conditions. Documentation or investigation of these tanks may be required.

- In a December 1992 Phase I document for the former Pfizer portion of the Site, excavation of mycelium and sulfuric acid heating coil-impacted areas was recommended. Reportedly, the mycelium and sulfuric acid impacted areas were excavated to visually clean soils. However, no endpoint samples were collected. Therefore, some shallow soil sampling is planned for this area.

- The Phase I report stated that asbestos and lead containing paint materials noted at the property were in good condition. Therefore, these materials were not identified as a

significant environmental concern. However, any potential construction or remediation activities should consider these materials.

- The Phase I report concludes that because the site has a long-term industrial nature and previous site operations are not readily apparent, local impacted areas may be present. Groundwater conditions up and downgradient of the Site, as well as shallow soil conditions, should be investigated. For this reason, several samplings are recommended at locations distributed across the site, rather than in designated source areas. The unknown site history is not a sufficient rationale to constitute a recognized environmental condition in our opinion, but the sampling described above will assess materials present at the site.

- The Phase I report mentions several containers of toxic or hazardous materials such as diesel fuel, foamite, tar, grease, etc. exist at the Site. Residual materials in storage tanks, such as ethylene glycol and petroleum, and lead containment liners should be properly disposed at an appropriate off site facility.

- The Phase I report concludes that floor penetrations at the south structure of the former Pfizer property may be potential sources. These locations will be inspected, traced if possible, and sampled if the penetrations discharge to onsite areas.

- Two elevated stainless steel tanks were discussed in the Phase I report. These tanks are situated in the tank filling structure and contained an unknown liquid. The size of the tanks is also unknown. No evidence of leakage or overfilling was discussed in the Phase I report. Therefore, these tanks will be inspected to evaluate their previous use. If the tanks contain residual materials, the residuals will be sampled, if possible, for waste disposal parameters so that potential remedial actions can be evaluated. Also, the volume of material remaining in the tanks will be estimated for disposal.

- Information provided by Con Ed has shown that product containing volatile organics was encountered in soil borings advanced for the cathodic protection installation associated with the 10,000 gallon UST. The VOCs detected included xylene and toluene. The source of these compounds has not been identified. Therefore, borings will be advanced within the vicinity of the UST to characterize the subsurface conditions in this area.

- An inventory of toxic/hazardous material on site including a material description, loeation and volume should be performed. This will be useful for formulation of any remedial action and associated cost estimate required in the Phase II Report.

3. FIELD INVESTIGATIONS

3.1 GEOPHYSICAL SURVEY

We recommend the use of a geophysical method to search for the suspected 550 gallon UST possibly located at the northern portion of the Pfizer property (Figure 1). Because the suspected location is vague, the area is not indicated on the site map. If the UST is not located, then no separate sampling may be necessary at that portion of the site. The geophysical methods proposed for this facility will be either ground penetrating radar, magnetometry, or a combination

of the two methods. During the geophysical survey, the suspect area (approximately 0.5 acre) will be traversed to identify subsurface anomalies. Any anomalies will be reviewed to determine the potential source of the readings. If an anomaly indicative of a UST is detected, soil borings or test pits will be advanced downgradient of the anomaly to evaluate the subsurface conditions.

3.2 SAMPLING OF BUILDING AND STRUCTURES

The site now contains three buildings: two (2) one-story buildings on the former Pfizer property and a building containing an office, control room and boiler house at the property adjacent to Kent Avenue. A manhole and two floor drains were identified in one of the former Pfizer site buildings. Both the floor drains and the manhole are believed to drain to the East River. The floor drains and the manhole will be inspected to document their integrity and probed to assess the bottom conditions. If sediment exists within the floor drains or manhole, the material will be sampled for TCL VOCs, SVOC, pesticides/PCBs, and TAL Metals and cyanide (Table 1). Specific analytical methods and detection limits are described in the QA/QC plan.

The sample collection will include use of either a hand auger or trowel, as appropriate to remove material from the floor drains/manhole as accessible. The portion of the sample collected for VOCs will be immediately transferred to laboratory supplied sample containers. A photoionization detector or equivalent will be used to obtain a headspace reading of the material. The remainder of the sample will be transferred to decontaminated stainless steel bowls, homogenized, and then transferred to the appropriate containers.

3.3 SURFACE SOIL SAMPLING

Because ASTs, existing buildings, surface cover the majority of the site remediated areas, and asphalt paved areas, surface soil samples will not be collected. Subsurface conditions will adequately represent near surface conditions.

3.4 SUBSURFACE SAMPLING

3.4.1 Site Set Up

Before any subsurface samples are collected, the utilities will be marked at the site. A utility clearance will be requested by contacting New York One-Call so that all known utilities are identified and that the utility companies are informed work is occurring in this area. In addition, a subcontract utility locating firm such as Eastern Locating will locate on-site utilities. The utility locating firm will use m-scopes or similar devices in an attempt to identify the orientations of potential utilities near the subsurface sampling activity. For an added precaution, the upper five feet of the sampling location will be excavated by non-mechanical means. Non-mechanical

excavation may be performed by hand excavating, super sucking, air lancing, or similar methods as appropriate. Proposed sampling locations may be adjusted if utilities limit access to a specific area.

To avoid excavation shoring (which is required at 5 feet for a person getting into the hole), an alternative plan is to excavate to 4.5 feet bgs, and then continue hand post augering in a smaller hole so that a fiberglass rod can be inserted approximately one foot below) to ensure utility clearance to 5.5 feet bgs.

3.4.2 Soil Borings

Thirteen (13) borings are proposed to be advanced at the site to the water table with soil and/or groundwater analyses to be performed. Because four (4) monitoring wells currently exist at the site, no additional permanent groundwater monitoring wells are specified. However, groundwater samples will be collected at four to six locations by either geoprobe or hydropunch sampling to evaluate potential groundwater impacts. Table 1 lists the boring number, its objective, and proposed analytes.

Soil samples will be collected using split spoon samplers or Geoprobe samplers, as appropriate. Continuous soil samples at 2 or 4 foot intervals will be collected from ground surface to the completion depth of the boring. Upon removal from the borehole, the headspace of the sample will be screened using a photoionization deteetor or equivalent. A portion of each soil interval sample will be retained in a resealable plastic bag and allowed to warm. After approximately 15 minutes, the headspace of the rescalable bag will be monitored using the PID with the measurement recorded on the boring log.

For this investigation, at least one and a maximum of three (3) samples per boring will be collected for chemical analyses. The soil samples submitted for chemical analysis will be determined during the field activities and will be based on the headspace measurements and field observations of staining or odors. If no unusual field observations occur and headspace readings are at background levels, only one sample will be collected and that depth will be immediately above the water table. If multiple sample intervals have elevated headspace and staining or odors, the samples submitted to the lab will be based on the field geologist's discretion with a bias to the intervals with the higher headspace measurements and heavy staining or odors.

Locations of all soil borings will be measured from existing and permanent site features. The measurements will be collected in a way that each location can be revisited if necessary. The measurements will be recorded in a field logbook or on a boring log as appropriate.

3.4.3 Groundwater Sampling

Groundwater samples will be collected following the specific procedures based on the appropriate drilling method (i.e., hydropunch or geoprobe). For this investigation, four (4) groundwater samples from borings (hydropunch/ geoprobe microwell) are proposed for collection. The location of these samples will be determined during the field activities and will be biased on the headspace results and field observations. If no elevated headspace readings are measured and no staining or odors noted, the groundwater samples will be collected at areas where potential sources are suspected. Table 1 indicates the suspected potential source areas where the groundwater samples may be collected.

Because this site has four existing monitoring wells, no monitoring well installations are planned. However, groundwater samples will be also collected from these existing wells to assess groundwater conditions at the site. Sampling results of base neutral compounds are available for these wells with the results indicating little or no compounds detected. Results for other parameters are either non-existent or not available. Therefore, groundwater will be sampled for VOCs, SVOCs, pesticides/PCBs, metals and cyanide.

The sampling activity will commence by opening the well and immediately collecting a headspace reading to assess any vapors that may be present. A depth to groundwater measurement will then be collected to determine the groundwater elevation and the amount of water to be removed for each well volume. Each well will be purged of 3 to 5 well volumes before the groundwater samples are collected. The purged groundwater will be contained in 55-gallon drums and handled following the waste handling procedures described below. Following purging, the wells will be allowed to recover until either 90% of the initial static water level or two (2) hours after completion of purging, whichever occurs first. Groundwater samples will be collected by lowering a dedicated polyethylene bailer below the water surface and then raising it from the well. The VOC containers will be filled first, followed by SVOCs, pesticides/PCBs, and metals/cyanide. A trip blank for VOCs will accompany the sample containers from the laboratory through the field sampling and delivery to the laboratory.

Based on the proximity of the site to the bulkhead, potential riprap, and subsurface concrete pads/foundations, the use of a drill rig may be preferred over Geoprobing. However, the Geoprobe will be used initially to limit the amount of drill cuttings generated during the subsurface sampling and to access tight areas where a drill rig may not be suitable.

All downhole equipment that is exposed to potentially impacted materials will be decontaminated before re-use at another location. Decontamination procedures are described below.

3.5 SURFACE WATER SAMPLING

No quantitative surface water sampling is recommended. However, during the site sampling activities, the bulkhead will be inspected on at least one occasion at low tide for any visual discharges. Any oil sheens or discolored leachate will be noted, sampled and tested.

3.6 SEDIMENT SAMPLING

A manhole and two floor drains within the truck weighing structure will be sampled provided sediment exists within these features. The approximate locations of the manhole and floor drains within the truck weighing station are shown on Figure 1. The purpose of the sediment samples is to assess the nature of materials that may have accumulated or passed through the drainage system during the previous site operations. For this investigation, three (3) sediment samples from the drains and manhole are proposed.

The floor drains will first be inspected to document their integrity, probed to assess the bottom, and then sampled if material is present. The sediment samples collected from the floor drains and/or manholes will be collected using a hand auger or equivalent. The hand auger will be advanced into the material and removed once material is retained within the sampling tool. Upon removal from the floor drain/manhole, a sample will be immediately collected for VOCs. The material will then be transferred to a decontaminated stainless steel bowl, homogenized and transferred to the appropriate laboratory supplied sample containers for SVOCs, pesticides/PCBs, and metals analyses. All equipment that has come in direct contact with the material that was sampled will be decontaminated before re-use.

No sediment samples will be collected from the perimeter of the site within East River. Sediment samples were previously collected following the Phase I of the Pfizer property. The results of these samples showed that sediments have the common constituents of the East River sediment.

4. SAMPLE HANDLING

All materials that are sampled will be transferred to laboratory supplied sample containers immediately following collection. In general, the portion of the sample collected for VOCs will be transferred to the sample containers first. Upon collection, each container will be labeled according to the sample identification. The parameter, date, time, person collecting the sample, preservative and site location will also be indicated on the sample label. The sample containers will then be placed in an iced cooler maintained at 4° Celsius. A chain of custody will be prepared to accompany the sample containers from collection through delivery to the laboratory. Sample coolers will be secured with chain of custody seals. All sample coolers will be delivered

to the analytical laboratory (Environmental Testing Laboratories) by overnight or laboratory provided courier as available. Any samples submitted to the laboratory will be protected by Bubble wrap or other packaging materials to limit potential container breakage. Coolers forwarded by overnight courier will be adequately secured with packaging tape to prevent the cooler from opening during shipment.

5. EQUIPMENT DECONTAMINATION

Before any onsite work occurs, a decontamination area will be constructed (pallets with plastic sheets over, etc.) to collect the rinse water or fluids generated during equipment decontamination. Any downhole equipment will be decontaminated before reuse at another location. Decontamination of drill rig equipment will include steam cleaning to remove particulates. The steam cleaning will occur in a decontamination pad so that the fluids generated by the process can be contained. Split spoon samplers will be washed with a non-phosphate detergent and rinsed with tap water.

To the extent practical, LMS will use laboratory decontaminated equipment during this project. However, if there is a need to decontaminate equipment during the field activities, the decontamination fluids will be contained. The decontamination process will include non-phosphate soap and water wash followed by a tap water rinse. Distilled water will then be used to remove the soap residue. Depending on the parameters to be sampled, additional rinsates may be used. A low pH acid will be used to decontaminate metals. Hexane will be used to decontaminate organics. If any rinsates are used, distilled water will be used to wash the rinsate. The equipment will then be allowed to air dry before re-use. Any contained decontamination fluids will be handled as described in the waste handling procedures proposed in the following section.

6. WASTE HANDLING

Any impacted (by visual, olfactory smell or other field screening observation) materials removed from the subsurface, either soil or water, will be containerized in drums provided by Con Ed. In addition, decontamination fluids will also be containerized. All containers will be labeled by date, material contained, source of the material at minimum and a contact name, organization, and telephone number. The containers will be stored in an area designated by the on-site Con Ed representative. Samples of the material contained in the drums will be collected and analyzed so that the material can be properly disposed of at a later date.

A temporary drum storage area will be constructed to contain any materials generated during the site investigation. Wastes generated at the North First Street property will be stored in a temporary waste storage area with proper secondary containment and limited access. The soil

and water will be characterized for waste disposal as described below. The drums will be labeled as investigative waste pending analysis.

The drums will be moved with a non-permitted vehicle or manually to the temporary storage area (maximum of one drum per shipment) after they have been properly secured and labeled.

The temporary storage area must accommodate at least 20 drums with appropriate aisle spacing of 2.5 feet for drum inspection. The temporary storage area will be constructed polyethylene sheeting (minimum 10-mil).

The drums must be stored on pallets to provide adequate inspection for leaks. Drums must not be stacked on top of each other and must be stored upright.

The drums must be securely closed when in storage. If the drum tips over and the contents cannot leak, the drum is considered securely closed.

Drums may be opened only to transfer material into or out of them.

The drum storage area must be inspected for leaks, spills, and drips on a daily basis.

Drums must be securely covered when in storage.

A drum log will be maintained indicating origin date, a general description of contents, any sampling of the drum contents, and daily inspections of the drum storage area.

Upon completing waste characterization, drums disposal will be arranged by Con Edison.

6.1 TYPES AND AMOUNTS OF WASTES

The following types and quantities of wastes are expected to be generated by each activity:

Activity	Location	Soil	Water
Boring locations	All locations	Less than one 5-gallon pail per location (Impacted soil only)	One or two 55-gallon drums from equipment decontamination
Sediment sampling	Truck weighing Station	No soil	10 gallons from washing the sampling tools
Well Sampling	Four existing monitoring wells	No soil	Two 55-gallon drums per well. One or two 55-gallon drums from equipment decontamination

6.2 WASTE CHARACTERIZATION ANALYSIS

Wastes generated during the investigation will be analyzed as indicated below:

Matrix	Analytical Method
SOLIDS	
TCLP-Organics (VOCs and SVOCs)	SW846
PCB	SW846
TCLP-metals	SW846
Total Petroleum Hydrocarbons	USEPA 418.1
LIQUIDS	
PCB	SW846
Flash-point	SW846
Total Organic Halogens	SW846
TCLP-Organics (VOCs and SVOCs) or EPA D018-D042 – Hazardous Waste Components List)	SW846

7. HEALTH AND SAFETY

A site-specific health and safety plan has been prepared for this site (see separate document). All personnel involved with the activities associated with this work plan will be required to read and sign the plan.

8. SCHEDULE

The activities associated with this plan are scheduled to begin on 29 November 1999. The fieldwork may extend to approximately 15 December 1999. However, the work may not be continuous throughout that time period. A draft report of the results will be provided by 21 December 1999.

QUALITY ASSURANCE PLAN

LMS maintains company policies and procedures to ensure that samples collected and any analytical analyses performed are completed with a high degree of quality. These policies and procedures ensure a high degree of confidence that the resulting data represent the matrix being sampled. QA/QC starts with the design of the sampling program and ends with the summarized analytical data submitted in the final report. This Quality Assurance Plan (QAP) describes all of these policies and procedures.

1 QUALITY ASSURANCE PLAN DESCRIPTION

The QAP is subdivided into eight sections as follows:

- ***QAP Organization and Responsibilities*** - This section identifies key personnel that are necessary for each activity during a study.

- ***Quality Assurance Plan Objectives*** - This section identifies the QA objectives set forth in this QAP. The following objectives are presented:

- QA/QC requirements
- Accuracy
- Precision
- Sensitivity
- Representativeness
- Completeness
- Comparability

- ***Field Sampling Procedures*** - This section describes LMS' sampling objectives for this project.

- ***Sample Custody*** – This section describes field and laboratory sample custody.

- ***Calibration and Maintenance Procedures*** - This section presents the calibration and maintenance procedures for field and laboratory equipment.

- ***Data Reduction, Review, and Reporting*** - Described here are the procedures that will be used to reduce, review, and report laboratory data.

- ***Data Assessment*** - Described in this section are the procedures used to assess the precision and accuracy of all environmental monitoring and measurement data.

- ***Corrective Actions*** - This section discusses the general procedures used when samples do not meet QA specifications.

2 ORGANIZATION AND RESPONSIBILITIES

To carry out an effective QAP, each individual responsible for a given component of the project must be aware of the QA objectives and procedures of his or her particular work and of the overall project. Responsibilities of project personnel follow:

2.1 Quality Assurance Officer (QAO) Responsibilities

The QAO is responsible for ongoing surveillance of project activities, for ensuring conformance to this plan, and for evaluating the effectiveness of its requirements. The QAO has access to any personnel or subcontractors, as necessary, to resolve technical problems and to take corrective action as appropriate and has the authority to recommend that work be stopped when that work appears to jeopardize quality. The QAO may periodically audit field activities and is available to respond to immediate QA/QC problems. The primary responsibilities of the QAO are to:

1. Monitor the correction of QC problems and alert task leaders where similar problems might occur.
2. Develop and maintain project QA files for sampling, monitoring, and field records.
3. Participate in QA audits.
4. Recommend changes to the project manager to improve the effectiveness of the project in attaining its QA objectives for field sampling and monitoring activities.
5. Review proposed additions and changes to this QAP.
6. Review deliverables for technical content and quality objectives.

2.2 Organization of QA/QC Tasks

Project QA will be maintained under the direction of the QAO, in accordance with this QAP. QC for the specific tasks will be the responsibility of the individuals and organizations listed below:

GENERAL RESPONSIBILITY	SCOPE OF WORK	RESPONSIBILITY OF QUALITY CONTROL
Field sampling	Supervision of environmental sampling	Project Geologist
Contract laboratory analyses	Analysis of water and soil samples by NYSDEC ASP procedures	Environmental Testing Laboratory
Data review	Review for completeness and Compliance	Dr. B.C. Williams

3 QAP OBJECTIVES

3.1 Overview

Quality data can be assured if the QA objectives set forth in this QAP are met. Data quality is measured by how well the data meet the QA/QC goals of the project. In this plan, "Quality Assurance" and "Quality Control" are defined as follows:

- ***Quality Assurance*** - The total integrated program for assuring reliability of monitoring and measurement data.
- ***Quality Control*** - The routine application of procedures for obtaining prescribed standards of performance in the monitoring and measurement process.

QA elements to be evaluated include accuracy, precision, sensitivity, representativeness, and completeness. Reporting of the data must be clear, concise and comprehensive. Other QC elements that are important to this project are blank contamination, instrument calibration, completeness of field data, sample holding times, sample preservation, and sample custody.

3.2 QA/QC Requirements

Data generated from the NYSDOH ELAP certified analytical laboratory will be used to assess environmental contamination, if present, at the Con Edison Project Sites. The QA requirements for all subcontracted analytical laboratory work performed on this project are described below. QA elements to be evaluated include accuracy, precision, sensitivity, representativeness, and completeness. The data generated by the analytical laboratory for environmental sample analyses are required to be sensitive enough to achieve detection levels low enough to meet required quantitation limits as specified in NYSDEC Analytical Services Protocol (NYSDEC ASP, 10/95). The analytical results meeting the required quantitation limits will provide data sensitive enough to

meet the DQOs of this investigation as described in the workplan. Reporting of the data must be clear, concise, and comprehensive. The QC elements that are important to this project are completeness of field data, sample custody, sample holding time, sample preservation, sample storage, instrument calibration and blank contamination.

- ***Initial Instrument Calibration*** - Calibration curves will be developed for each of the compounds to be analyzed. Standard concentrations and a blank will be used to produce the initial curves. The development of calibration curves and initial calibration response factors must be consistent with method requirements presented in the most recent version of NYSDEC ASP (10/95).

  For Target Analyte List (TAL) metals, an atomic absorption calibration curve is obtained with the use of a blank and at least three calibration standards which cover a range of concentrations appropriate for the sample, for each metal analyzed. One atomic absorption standard must be at the contract required quantitation limit (CRQL), with the exception of mercury. For ICP systems, the instrument will be calibrated according to the manufacturer's recommendations; at least two standards must be used. Results for the standards must be within ±5% of the true value and will be evaluated using NYSDEC ASP criteria.

- ***Continuing Instrument Calibration*** - The initial calibration curve will be verified by the analytical laboratory every 12 hrs by analyzing one calibration standard. The standard concentration will be the midpoint concentration of the initial calibration curve. The calibration check compound must come within 25% relative percent difference (RPD) of the average response factor obtained during initial calibration. If the RPD is greater than 25%, corrective action must be taken as provided in the specific methodology.

  TAL initial calibration curves will be verified by analyzing a standard at every wavelength used for a given analyte, at a frequency of 10% or every 2 hours during an analysis run, whichever is more frequent. The standard used for continuing calibration purposes will be at or near the mid-point concentration of the calibration curve. Deviations of the continuing calibration standards from the original curve must be within control limits and will be evaluated using NYSDEC ASP criteria.

- ***Method Blanks*** - Method blank or preparation blank is prepared from an analyte-free matrix that includes the same reagents, internal standards and surrogate standards as the related samples. It is carried through the entire sample preparation and analytical procedure. A method blank analysis will be performed once for each 12 hr period during the analysis of samples for volatiles and once for each batch or 20 samples (whichever is most frequent) for semivolatiles and metals. An acceptable method blank will contain less than five (5)

times the CRQL of methylene chloride, acetone, and 2-butanone. For all other target compounds, the method blank must contain less than or equal to the CRQL of any single target compound. For non-target peaks in the method blank, the peak area must be less than 10% of the nearest internal standard. The method blank will be used to demonstrate the level of laboratory background and reagent contamination that might result from the analytical process itself.

- ***Field Blank*** - A field blank consists of two sets of identical, laboratory-cleaned sample containers. The first set is filled at the laboratory with deionized laboratory-grade water. The water used is from the same source as that used for the laboratory method blank. In the field, this water will be passed through the field sampling equipment into an additional second set of containers that will then be taken back to the laboratory to be analyzed for the compounds of interest. The purpose of a field blank is to determine whether the field sampling equipment is cross-contaminating samples and a single field blank will be collected for each day of field activities

- ***Trip Blank*** - Trip blanks consist of a single set of sample containers filled at the laboratory with deionized, laboratory-grade water. The water used will be from the same source as that used for the laboratory method blank. The containers will be carried into the field and handled and transported in the same way as the samples collected that day. Analysis of trip blanks for volatile organic compounds (VOCs) are used to identify contamination from the air, shipping containers, or from other items coming in contact with the samples. A complete set of trip blanks will be provided with each shipment of samples to the certified laboratory.

- ***Duplicates*** - Duplicate samples are two or more samples considered representative subsamples of the same source. The samples are identically processed throughout the measurement system. A groundwater or soil field duplicate (blind duplicate) will be analyzed for the appropriate parameters. Laboratory duplicate analyses will be performed on liquid and solid matrices at a rate of one for every twenty (20) field samples. The results of the duplicate analyses will be used to assess the precision of the measurement systems.

- ***Surrogate Spike (SS) Analysis*** - Surrogate standard determinations will be performed on all samples and blanks analyzed by the analytical laboratory. All samples and blanks will be spiked with the appropriate surrogate compounds (as indicated by the methodology) before purging or extraction in order to monitor preparation and analyses of samples. Surrogate spike recoveries shall fall within the advisory limits in accordance with the NYSDEC ASP protocols for samples falling within the quantitation limits without dilution.

- ***Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank (MS/MSD/MSB) Analysis***

  MS, MSD and MSB analyses will be performed to evaluate the matrix effect of the sample upon the analytical methodology along with the precision of the instrument by measuring recoveries. The MS/MSD/MSB samples will be analyzed for those organic at a rate of one for approximately every 20 field samples of a similar matrix. The RPD will be calculated from the difference between the MS and MSD recoveries.

  Matrix spike blank analysis will be performed to indicate the appropriateness of the spiking solution(s) used for the MS/MSD.

- ***Spike and Duplicate Analyses***. Spike and duplicate analyses will be performed to evaluate the matrix effeet of the sample upon the analytical methodology along with the precision of the instrument by measuring recoveries. The spike and duplicate samples will be analyzed for TAL metals plus cyanide at a rate of one for approximately every 20 field samples.

3.2.1 **Accuracy**

Accuracy is defined (SW846, 3rd ed.) as "the nearness of a real or the mean (x) of a set of results to the true value. Accuracy is assessed by means of reference samples and percent recoveries." Accuracy includes both precision and recovery and is expressed as percent recovery (%REC). The matrix spike sample is used to determine %REC. The laboratory calculates %REC from the results of the MS samples. These results are used to assess the effect of matrix interference on the laboratory's ability to detect environmental contaminants. The MS %REC is calculated by the following equation:

$$\%\ REC = \frac{SSR - SR}{SA} x\ 100$$

where:

SSR = Spike sample results
SR = Sample results
SA = Spike added from spiking mix

3.2.2 **Precision**

Precision is defined (SW846, 3rd ed.) as "the measurement of agreement of a set of replicate results among themselves without assumption of any prior information as to the true result.
Precision is assessed by means of duplicate/replicate sample analyses."

Analytical precision is expressed in terms of RPD. The RPD is calculated using the following formula:

$$RPD = \frac{D_1 - D_2}{(D_1 + D_2)/2} \times 100$$

where:

RPD = Relative percent difference
D_1 = First sample value
D_2 = Second sample value (duplicate)

3.2.3 **Sensitivity**

The sensitivity objectives for this plan require that data generated by the analytical laboratory achieve quantitation levels low enough to meet the required detection limits specified by NYSDEC ASP (Table 1).

3.2.4 **Representativeness**

Representativeness is a measure of the relationship of an individual sample taken from a particular site to the remainder of that site, and the relationship of a small aliquot of the sample (i.e., the one used in the actual analysis) to the sample remaining on site. The use of standardized techniques and statistical sampling methods influences the representativeness of an aliquot of sample to the sample at the site.

3.2.5 **Completeness**

Completeness is a measure of the quantity of data obtained from a measurement system as compared to the amount of data expected from the measurement system. Completeness is defined as the percentage of all results that are not affected by failing QC qualifiers, and should be between 70 and 100% of all analyses performed. The objective of completeness in laboratory reporting is to provide a thorough data support package. The laboratory data package provides documentation of sample analysis and results in the form of summaries, QC data, and raw analytical data. The laboratory will be required to submit data packages that follow NYSDEC ASP reporting format that, at a minimum, will include the following components:

1. All sample chain-of-custody forms.
2. The case narrative(s) presenting a discussion of any problems and/or procedural

changes required during analyses. Also presented in the case narrative are sample summary forms.

3. Documentation demonstrating the laboratory's ability to attain the contract specified detection limits for all target analytes in all required matrices.

4. Tabulated target compound results and tentatively identified compounds.

5. Surrogate spike analysis results (organics).

6. Matrix spike/matrix spike duplicate/matrix spike blank results.

7. Spike and duplicate results.

8. QC check sample and standard recovery results.

9. Blank results (field, trip, and method).

10. Internal standard area and RT summary.

3.2.6 **Comparability**

Comparability is the degree to which analytical data generated from an individual laboratory can be compared with those from another laboratory in terms of use of standardized industry methods and equivalent instrumentation and techniques. No split samples are expected to be taken for this project.

4 FIELD SAMPLING PROCEDURES

The specific procedures for the different field sampling protocols to be used are provided in the site-specific field sampling plan. All field teams will be required to adhere strictly to the procedures provided in the work plans. Prior to field activities, all site personnel will be trained in health and safety techniques and site-specific operations in order to conform with the site specific project Health and Safety Plan (HASP).

The objective for all sampling is to obtain samples that are characteristic of the site and the medium being sampled (e.g., soil, water and sediments). Established sampling protocols are used to:

1 Prevent cross contamination between sampling points.

2 Obtain a fresh sample.

3 Obtain a sample representative of the medium sampled.

4 Ensure, by appropriate and timely preservation of the sample, that the analytical results are reliable.

5 Document the sampling point in space and time.

5 SAMPLE CUSTODY

The handling of samples in the field and in the laboratory will conform to sample custody procedures presented in this section. Field custody procedures involve proper sample identification, chain-of-custody forms, and packaging and shipping procedures. Laboratory custody begins with the receipt of samples at the laboratory and continues through sample storage, analysis, data reporting, and data archiving. This section provides the procedures that will be followed during the course of the project to ensure proper sample custody.

5.1 Field Custody Procedures

The following elements are important for maintaining the field custody of samples:

1. Sample identification
2. Sample labels
3. Custody records
4. Shipping records
5. Packaging procedures

Sample labels are attached to all sampling bottles before field activities begin and each label will contain an identifying number. A numbering system is used to prevent duplicate identification. Each number has a suffix that identifies the site from which the sample was taken. Approximate sampling locations are marked on a map with a description of the sample location. The number, type of sample, and sample identification are entered into the field logbook.

A chain-of-custody (COC) form is initiated at the laboratory and accompanies the sample bottles from the laboratory into the field. Upon receipt of the bottles and cooler, the sampler signs and dates the first "Received" blank space. After each sample is collected and appropriately identified, entries are made on the chain-of-custody form that will include:

- Site name and address
- Samplers' names and signatures
- Names and signatures of persons involved in chain of possession

- Sample number
- Number of containers
- Sampling station identification
- Date and time of collection
- Type of sample and the analyses requested
- Preservatives used (if any)
- Pertinent field data (pH, temperature, turbidity, etc.)

After sampling has been completed, the sampler will return the samples to the laboratory. The sampler will sign and date the next "Relinquished" blank space. One copy of the custody form will remain in the field and the remaining copies will accompany the samples to the laboratory. All samples will be received by the laboratory within 48-hrs of collection. Samples will be received by laboratory personnel, who will assume custody of the samples and sign and date the next "Received" blank.

5.2 Laboratory Custody Procedures

Upon receipt by the analytical laboratory, samples will proceed through an orderly processing sequence specifically designed to ensure continuous integrity of both the sample and its documentation.

All samples will be received by the laboratory's sample control group and will be carefully checked for label identification and complete and accurate chain-of-custody records. The sample will be tracked from storage through the laboratory system until the analytical process is completed and the sample is returned to the custody of the sample control group for disposal. Generally, access to NYSDOH ELAP certified laboratories are restricted to prevent unauthorized contact with samples, extracts, or documentation.

6 CALIBRATION AND MAINTENANCE PROCEDURES

6.1 Field Equipment

The calibration of each instrument is checked prior to each day's use. Date and time of the calibration check, serial and model number, and signature of the calibrating technician are entered into the field logbook. If the instrument readings are incorrect, the instrument is either recalibrated by the technician or returned to the LMS warehouse. At the warehouse the technical equipment

coordinator will calibrate and/or repair the instrument as necessary. For major overhauls the instruments are returned to the manufacturer.

Preventive maintenance of field equipment is performed routinely before each sampling event; more extensive maintenance is performed based on hours of use. The LMS Equipment Coordinator under the supervision of the Laboratory Director has overall responsibility for the preventive maintenance program.

6.2 **Laboratory Equipment**

The calibration procedures for the analytical equipment used by the off-site analytical laboratory will follow instrument manufacturer's recommendations and guidelines established for NYSDEC ASP (October 1995). The maintenance procedures for the analytical equipment used by the subcontracted laboratory will follow manufacturer's instructions.

7 ANALYTICAL PROCEEDURES

Analytical procedures for each of the Con Edison Sites are described in detail in the site-specific field sampling plans. All analytical procedures are in accordance with NYSDEC ASP (10/95). A summary of anticipated analytical methods and protocol are presented in Table 2. The required holding times and preservation methods for each analytical fraction are provided in Table 3. The type and frequency of quality control samples for each type of matrix sampled is discussed in Section 3.1.

8 DATA REDUCTION, REVIEW AND REPORTING

The process of data reduction, review, and reporting ensures that assessments or conclusions based on the final data accurately reflect actual site conditions. This plan presents the specific procedures, methods, and format that will be employed for data reduction, review, and reporting of each measurement parameter determined in the laboratory and field. Also described in this section is the process by which all data, reports, and work plans are proofed and checked for technical and numerical errors prior to final submission.

8.1 **Data Reduction**

Data reduction is the process by which raw analytical data generated from the laboratory instrument systems are converted into usable mass concentrations. The raw data, which may take the form of area counts, instrument responses, or observations, are processed by the laboratory and converted into concentrations expressed in μg/kg (ppb) for soil samples and ug/l (ppb) for water samples.

TABLE 2

ANALYTICAL SUMMARY TABLE

Con Edison Phase II Investigations

MATRIX	ANALYSIS	PROTOCOL ASP	METHOD
Solids and Water	VOCs		8260
	SVOCs		8270
	Pesticides		8081
	PCBs		8082
	TAL Metals		6000/7000
	CN-1		335.2

TABLE 3

CONTAINERS, PRESERVATIVES, AND HOLDING TIMES
NYSDEC ASP, 10/95 REVISION
Con Edison Phase II Investigations

PARAMETER	CONTAINER	PRESERVATIVE	MAXIMUM HOLDING TIME
VOCs	Glass, teflon lined septa	4° C[1]	7 days
SVOCs	Glass, teflon lined septa	4° C	5 days after VTSR* until extraction; 40 days for analysis
Pest/PCBs	Glass, teflon lined septa	4° C	5 days after VTSR* until extraction; 40 days for analysis
TAL Metals (except mercury)	Plastic, glass	HNO_3 to pH<2	6 months
Mercury	Plastic, glass	HNO_3 to pH<2	26 days
Total Cyanide	Plastic, glass	4° C, NaOH to pH > 12	12 days

* - Verified time of sample receipt.
- HCL will not be used to preserve water samples for VOCs.

Data reduction also includes the process by which raw field data are summarized in tables and graphs, from which quantitative or qualitative assessments can be derived by further integration and evaluation.

Field data obtained during sampling are summarized on appropriate field forms. This information is used to assess field conditions at the time of sampling and is summarized and analyzed along with the chemistry data in the final report. Occasionally, the reduction of actual field data requires correcting measurement data for the measurement system's baseline value. The data will be adjusted only after the raw data has been submitted to LMS' QAO and prior to preparation of the final report.

8.2 Review

LMS' QAO will review the data prior to use in the reports. The QAO will evaluate the analytical laboratory's ability to meet the DQOs.

8.2.*1* ***Field Data.*** Data collected and/or reduced in the field will be reviewed initially for correctness of format, calculation, and completeness by the crew chief. The criteria used to review field data will include the following:

- Checking to see that inventory and station numbers are correct
- Checking to see that specified sampling and preservation methods were followed
- Verifying that sufficient sample volume is collected to conduct requested analyses
- Noting any anomalies or unusual circumstances in data sampling and collection
- Verifying that calibration procedures were followed
- Verifying that data are reported in correct units
- Checking 100% of all field calculations
- Verifying that samples were properly shipped with the appropriate chain-of-custody documentation
- Verifying that QC samples were prepared and taken

Further review of such data will be performed by the LMS crew chief prior to data integration and evaluation. All assigned data reduction or analytical procedures will be verified for accuracy and content by at least two professionals qualified and experienced in evaluating the particular technical specialty.

8.2.2 ***Analytical Laboratory Report Review.*** The QAO or designee, under the QAO's supervision, will review each analytical data package for completeness (i.e., have all the analyses requested been performed) and general protocol compliance. If information is found to be missing from the data package the analytical laboratory will be contacted and requested to submit any lacking information.

8.3 Reporting

8.3.1 ***Field Data Reporting.*** All field measurements and observations will be recorded in project logbooks or field data records. All data will be recorded directly and legibly into field logbooks, with all entries signed and dated. If entries are changed, the change will not obscure the original entry. The reason for the change will be stated, and the correction and explanation will be signed and dated at the time the correction is made. Field data records will be organized into standard formats whenever possible, and retained in permanent files.

8.3.2 ***Laboratory Data Reporting.*** All sample data packages submitted by the analytical laboratory will be required to be reported in conformance to the NYSDEC ASP (10/95) Category B data deliverable requirements. The analytical laboratory test reports for all samples submitted will contain the following information:

1. Date of sampling
2. Description of samples
3. Description of analytical method
4. Analytical results of all samples plus field and method blanks
5. Results of duplicate and spike analyses
6. Method detection limits and precision and accuracy statements for parameters analyzed

9 INTERNAL QUALITY CONTROL

9.1 Overview

QC checks will be performed to ensure the collection of representative and valid data. Internal QC refers to all data compilation and contaminant measurements. QC checks will be used to monitor project activities to determine whether QA objectives are being met. All specific internal QC checks to be used are identified in this section.

9.2 **Field Quality Control**

On each day of field sampling, approximately 5% of field measurements will be checked by duplicate measurement. The crew chief will spot-check sampling procedures and containers to check against possible contamination. The crew chief will double-check that all sample containers are properly sealed and labeled and that all field forms, including the chain-of-custody forms, are properly completed, dated, and signed.

After fieldwork is completed, a comparison of field and trip blank data will be used to check on the quality of the fieldwork. Also, the results of duplicate and spiked samples will be used to check on the accuracy of sampling techniques. If the QAO and crew chief find that corrective action is needed, such action will be implemented immediately. If the analysis of field and trip blanks indicates extensive contamination, resampling may be necessary.

9.3 **Analytical Laboratory Quality Control**

The analytical laboratory is required to exercise internal control in a manner consistent with the requirements of this plan. Control checks and internal QC audits are required by the NYSDEC ASP methods. These include reference material analysis, blank analysis, MS/MSD, spike and duplicate analysis, cleanups, instrument adjustments and calibrations, standards, and internal audits.

The laboratory will perform the QC checks with the following frequency:

- Reagent and method blanks will be analyzed at a rate of one per batch.
- One MS, one MSD and one MSB will be analyzed per 20 samples for organics.
- One Spike and Duplicate will be analyzed per 20 samples for inorganics.
- Performance evaluation samples will be analyzed at a rate of once per calendar quarter.

10 OFFICE QUALITY CONTROL

10.1 **Technical Checks**

One qualified professional will proof and check all final reports for technical errors and/or inconsistencies. Twenty percent of all final reports will be subsequently checked again by a qualified professional. Checks will be made of all references and protocols cited to ensure they are correct. Procedural descriptions will be reviewed to ensure they are accurate with referenced protocol.

10.2 Numerical Checks

One qualified professional will proof and check all final reports for transcription and/or calculation errors. Twenty percent of all final reports will be subsequently checked again by a qualified professional. All data will be checked to ensure no transcription errors have occurred. Data tables will also be checked to see that any criteria cited for comparison purposes is appropriate and correctly referenced. All calculations will be checked to ensure that they will be properly presented and that resulting values are achievable. If any results cannot be duplicated the calculations will be independently checked for accuracy.

11 PERFORMANCE AND SYSTEMS AUDITS

Performance audits, when performed, will be used to monitor project activities to assure compliance with project DQOs. The following text summarizes the field audits that are conducted periodically.

11.1 Field Audits

Internal audits of field activities are periodically conducted by LMS. Where subcontractors are used for field activities, LMS will assume overall responsibility for the field procedures used. All field activities will be routinely monitored by the LMS on-site crew chief to ensure that work is done correctly. Field audits will be periodically conducted by LMS' QAO to ensure that appropriate procedures are being utilized by all crews. All sampling and analyses work will be reviewed routinely by the crew chief in charge of the particular task. All data sheets obtained in the field will be initialed and dated by crew chief after review and acceptance of the services performed.

Any field audit performed will include monitoring and evaluation of sample collection, sample holding times, preservation techniques, field QC, and equipment calibration. These audit forms will be kept on file with LMS' QAO for one year after completion of the project, then will be transferred to storage and held for an additional five years.

11.2 Analytical Laboratory Audit

Laboratory audits are not required for the project. The analytical laboratory must maintain complete NYSDOH ELAP certification throughout the project. If required, a performance and system audit will be conducted by LMS on the subcontracted laboratory. The audit will assess the laboratory capacity and capability with respect to the objectives of this project. The results and

conclusions of the laboratory audit will be kept on file with LMS' QAO for one year after project completion, then will be transferred to storage and held for an additional 5 years.

12 CORRECTIVE ACTION

12.1 Field Corrective Action

In the event a field audit is conducted by LMS' QAO, instances of nonconformance will be identified and reported to the LMS project manager, who will initiate corrective actions, if necessary. These actions can range from altering solvent washes used in decontamination to changing the sampling strategy to obtain representative samples. The project QAO and the project manager will have the ability to stop all work if audit results warrant such action.

12.2 Analytical Laboratory Corrective Action

Corrective actions will be implemented if unsatisfactory performance and/or system audit results indicate that problems exist. Corrective action may also be implemented if the results of a data assessment or internal QC check warrants such action.

Instances of nonconformance identified in internal audits or by data assessments will be addressed by taking corrective action. Such action(s) will be initiated by the analytical laboratory QA manager who is responsible for assessing the action for its appropriateness and completeness. The QA manager will also be responsible for filing a noncompliance report to laboratory management. QC charts will be used to monitor day-to-day variations in precision and accuracy.

Short-term corrective actions will be initiated as a result of malfunctioning equipment or improper use of analytical methodologies. Long-term actions will be initiated through the laboratory QAO who assigns personnel to investigate the problem. A series of evaluations will then follow to assure the action is appropriate and the results complete.

13 REPORTS TO MANAGEMENT

13.1 Overview

An important aspect of the QA/QC program is the communication between the QA department and upper management. Regular appraisal by management of the quality aspects related to data gathering efforts will provide the mechanism whereby the established objectives will be met.

Reports to management will include:

- Periodic assessment of measurement data accuracy, precision, and completeness
- Results of performance audits
- Results of system audits
- Significant QA/QC problems and recommended solution
- Resolutions of previously stated problems

13.2 **Field Activities**

LMS will be responsible for documenting the results of all field audits. Audit results will be documented in the logbook for field audits. Status reports will be periodically submitted to describe the progress of the project. These will include compiled field data sheets, schedule corrective action documentation at appropriate intervals, and progress of the actions.

13.3 **Analytical Laboratory**

Laboratory noncompliance reports will be filed with the laboratory project manager. These reports will include a summary of accuracy and precision data, quality problems, and the status of any corrective actions implemented.

Meetings will be held between the laboratory management and the laboratory QA personnel to alert the appropriate staff of problems needing corrective action. The laboratory will submit a case narrative with each set of sample analyses. The narrative will describe any QA/QC problems encountered during sample analysis and any corrective actions taken by the laboratory.

Route to Hospital

Figure 1

DATE OF HEALTH AND SAFETY PLAN PREPARATION: November 12, 1999 (revised November 23, 1999)

TASK DESCRIPTION:

The objective of the project is to determine the presence/absence and if present evaluate the extent of contamination in the subsurface soil, sediment, and groundwater.

1) Installation of borings and collection of subsurface soil samples; analysis of soil samples for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides/PCBs, metals, and cyanide.
2) Collection of groundwater samples; analysis of groundwater samples for VOCs, SVOCs, pesticides/PCBs, metals, and cyanide.
3) Collection of sediment samples and analysis of the sediment samples for VOCs, SVOCs, pesticides/PCBs, metals, and cyanide.

PROJECT SCHEDULE:

The field work is scheduled to start on November 29, 1999 and be completed by December 15, 1999 with the draft report submitted by December 21, 1999.

HAZARDOUS/SUBSTANCES (known or suspected, contaminated media or in storage container, etc.):

PCBs in soil and potentially in sediment and groundwater. Other substances that may be encountered include ethylene glycol, sulfuric acid, asbestos, lead-based paint, mycelium, and other petroleum products.

HAZARD ASSESSMENT (toxic effects, including TLVs, IDLHs, reactivity, stability, flammability, and operational hazards with sampling, decontaminating, etc):

Chemical hazards may be encountered as part of this investigation. Table 2 provides information on specific chemical compounds that may be encountered during the field investigation. Air monitoring will be performed utilizing an HNU photo-ionization detector (PID) or equivalent and combustible gas indicator (CGI) to monitor for the presence or absence of atmospheric organic chemical compounds. Slip/trip hazards are always a possibility in any type of fieldwork and will be evaluated and removed if deemed necessary. Overhead/subsurface hazards may exist which would impact drilling of soil borings and monitoring wells. All utilities must be marked out in detail prior to the commencement of any drilling activities. Noise associated with use of the drilling equipment may be excessive (above 85 dB), therefore, ear plugs or ear muffs will be used as a precaution. Since the work is scheduled to be done in late fall, cold stress may be a hazard. Workers will wear appropriate clothing such as gloves and hard hat liners as protection against the cold. Each person will monitor their buddy for symptoms of hypothermia, i.e., shivering, vague or slurred speech, memory lapses, immobile or fumbling hands, lurching or a stumbling gait, drowsiness, or the inability to get up after a rest. Treatment includes getting the person out of the cold quickly, give warm liquids, dry clothes, and a blanket. Each person will also monitor their buddy for signs of frostbite, i.e., yellow or whitish skin. The easiest treatment for frostbite is to place the bare hand over the frostbitten part and to keep the part covered subsequently. The area should never be rubbed. The potential presence of mycelium presents a potential biological hazard. Table 3 provides a list of tasks, summarizes the hazards associated with the tasks, and provides the personal protective equipment (PPE) that will be employed. Also provided on the table is the action levels for the HNU and CGI that will be used to upgrade the level of protection.

SITE WORK ZONES (designate exclusion zone, contamination reduction zone and support zone):

See Figure 2. The exclusion zone is defined as the area where the actual work or samples will be collected. It is also the area where contact with contaminated material may occur. For this project it is defined as a 20-ft radius around each sample point. The contamination reduction zone (decontamination area) is the area where personal and equipment decontamination will take place. The support zone is located in a clean area of the site.

TABLE 3 (page 1 of 2)
HAZARD ANALYSIS/HAZARD ASSESSMENT
Con Edison North First Street Site

Note: Air Monitoring will be conducted using an HNU photo-ionization detector and combustible gas indicator. Action levels to be used are:

- CGI - if the reading on the CGI is >10% of the LEL work will stop until engineering controls, i.e., ventilation can be used to reduce the LEL.
- HNU - if the reading on the HNU is >5 units in the breathing zone for more than 5 min. upgrade to Level C respiratory protection will be used (full-face air purifying respirator fitted with combination organic vapor and HEPA cartridge.

SITE ACCESS (describe procedures to control site access):

The on-site HSO will keep a log book that will require everyone to sign in and out of the facility, on a daily basis (including all subcontractors and Consolidated Edison personnel). The HSO/OSC will meet with the Consolidated Edison representative when necessary to obtain any work permits or discuss any other project related activities.

MONITORING PROCEDURES TO BE PERFORMED: Monitoring the site for identity and concentration of contamination in all media:

The breathing zone (4-5 ft above the ground surface) will be monitored at least hourly or on a more frequent basis if changing conditions are noted using the HNU and/or CGI during designated activities (see Table 3).

Medical monitoring procedures:

All LMS employees who regularly are in the field receive an annual physical that is consistent with the requirements contained in 29CFR1910.120 (f). Any employee who may have to wear a respiratory has been medically certified to be able to wear one and has also been fit-tested. Fit-testing certificates (for those employees that may wear a respirator) and annual physical records are provided for all personnel that will be working on site.

Personnel monitoring procedures:

Not needed for this project.

DECONTAMINATION AND DISPOSAL

Decontamination Procedures (including contaminated personnel, surfaces, materials, instruments, equipment, etc.):

All sampling equipment, i.e. stainless steel spoons, etc. will be decontaminated at the LMS laboratory by washing with Alquinox detergent, rinsed with potable water, rinsed with a suitable solvent such as Hexane, rinsed with deionized water and air dried, prior to the commencement of on-site sampling activities. Drilling equipment, i.e., split-spoons, augers, will be steam cleaned between boreholes and split-spoons will be cleaned prior to re-advancement into a borehole, to prevent cross contamination. Groundwater samples will be collected using dedicated disposable bailers. Submersible pumps will be deeontaminated between monitoring well locations by running clean water through it; dedicated tubing will be used. All personnel will wash with soap and water after work is completed.

Disposal Procedures (contaminated equipment, supplies, disposables, washwater):

All decontamination water and drill cuttings (if evidence of contamination is observed) will be drummed and stored on site for subsequent disposal by Consolidated Edison. The drums will be stored at the locations shown on Figure 1. It is anticipated that the project will generate approximately 600 gallons of water and 5 yd^3 of soil that will be placed into thirteen 55-gal drums that will be provided by Consolidated Edison. Development and purge water generated from the monitoring wells will be containerized in properly labeled drums, characterized and shipped off-site. Disposable personal protective clothing will be put in bags and then stored in, properly labeled, 55 gallon drums, which will be provided by Consolidated Edison. Solid wastes will be sampled and analyzed for TCLP-benzene, PCs, TCLP-metals, and total petroleum hydrocarbons. Liquid wastes will be sampled and analyzed for PCBs, flash-point, total organic halogens, and TCLP-Organics (VOCs and SVOCs). Consolidated Edison will be responsible for disposing of all material generated by the project.

CHEMICAL PRODUCTS:

The following chemicals will be used during the course of the project. Material Safety Data Sheets (MSDS) for each of these chemicals are attached to this health and safety plan.

Chemical	Use	Quantity	NYCDEP/USEPA
Nitric Acid	Preservative	<100 ml	Yes
Sodium Hydroxide	Preservative	<100 ml	Yes
Hexane	Decon Chemical	<1 gal	Yes
Alquinox	Decon Chemical	<1 gal	No

PERMITS:

The following permits will be required to have on-site in order to conduct any work at the North First Street property: Consolidated Edison Work Permits.

EMERGENCY PROCEDURES

In event of personnel exposure (skin contact, inhalation, ingestion) the following three procedures will be implemented:

Skin Contact - Wash with soap and water.
Inhalation - Remove to fresh air, monitor for ABCs.
Ingestion - Call Poison Control Center and monitor ABCs.

In the event of personnel injury:

Check ABCs (Airway, Breathing and Circulation). Perform First Aid, CPR, or rescue breathing, if required. Call 911, if professional help is deemed necessary. At least one LMS person on-site is currently certified in American Red Cross Standard First Aid and Adult CPR.

In event of potential or actual fire or explosion:

Evacuate to Support Zone (see Figure 1 for evacuation plan). HSO will check log book to make sure that all personnel are accounted for before leaving site. Fire department to be contacted in case a fire breaks out.

In event of potential or actual ionizing radiation exposure:

Not Applicable.

In event of environmental accident (spread of contamination outside sites):

Stop spread of chemical as best as possible and contact Consolidated Edison Shift Supervisor and/or Field Representativeimmediatedly.

COMMUNICATION:

The buddy system will be employed. If there is a need to communicate between crew members walkie-talkies will be used. An air horn will be used to signal emergencies. Three long air horn blasts will signal that the site will be evacuated; the crew should stop work immediately, shut off equipment immediately and proceed to the support zone. Ten short air horn blasts will signal that there is a medical emergency. The person responsible for administering first aid will immediately report to the support zone to determine the nature of the medical emergency and take the necessary steps to care for the person. If walkie-talkies are being used, then the first aid person will respond via the walkie-talkie to determine the location and nature of the emergency, and then take the necessary steps to care for the person.

EMERGENCY EQUIPMENT:

A first aid kit that is also equipped with a CPR microshield and fire extinguisher will be available at all times during field work. The field crew will also be equipped with a cell phone and pager. In addition, absorbent pads (spill kit) will be available on-site to contain any spills that may occur.

PERSONNEL POTENTIALLY EXPOSED TO HAZARDOUS SUBSTANCES (As Applicable):

PERSONNEL POTENTIALLY EXPOSED TO HAZARDOUS SUBSTANCES (As Applicable):

Personnel authorized to enter site: See Table 1.

ALTERNATIVE WORK PRACTICES

(Describe alternative work practices or instruments not specified in this form. Indicate work practices specified in the chapter for which proposed alternative work practices will serve as substitute).

Prior to drilling all utilities will be marked out. It is not anticipated that the project will require any welding or confined space procedures. Test pits will be excavated with non-mechanical devices to clear utilities, therefore, the requirements for excavation contained in 29CFR1926.650-652 will be followed.

TASK-SPECIFIC LEVEL OF PROTECTION AND ACTION LEVELS

(see attached table 3 including specific description of protective gear and action levels to upgrade or downgrade LOP)

See Table 3.

SITE MAP

(Attach a site map. Map should be properly scaled and keyed to local landmarks).

See Figure 2.

TRAINING

(Provide description of minimum training, reference OSHA Sections).

At least two people will be onsite at all times. At a minimum one person shall have updated supervisory training as specified in 29CFR1910.120 e(4). All other personnel shall have at least the 40-hr updated training as specified in 29CFR1910.120 e(3). All personnel shall also have an up-to-date annual refresher as specified in 29CFR1910.120 e(8). If respirators are to be worn the personnel shall be trained in their use as specified in 29CFR1910.134. All of the training certificates for the above training will be available on-site, for each and every employee that will be participating in the scope of work. Table 1 provides a list of personnel and their training levels. In addition, at least one person on site will be trained in standard first aid and CPR.

AFFIDAVIT

All personnel who will be entering the exclusion zone must sign attached affidavit. LMS personnel must also read and comply with LMS' generic HASP.

AFFIDAVIT

I, _____ (name) of _____, (company name) have read the Health and Safety Plan (HASP) for the North First Street site. I agree to conduct all on site work in conformity with the requirements of the HASP. In addition, I acknowledge that failure to comply with the designated procedures in the Health and Safety Plan will lead to removal of me from the site.

Document #111

MATERIAL SAFETY DATA SHEET

I. IDENTIFICATION

Product Name (As appears on label)	**ALCONOX®**
CAS Registry Number	Not Applicable
Effective Date	January 1, 1998
Chemical Family	Anionic Powdered Detergent

II. HAZARDOUS INGREDIENTS/IDENTITY INFORMATION

There are no hazardous ingredients in ALCONOX® as defined by the OSHA Standard and Hazardous Substance List 29 CFR 1910 Subpart Z.

III. PHYSICAL/CHEMICAL CHARACTERISTICS

Boiling Point (F):	Not Applicable
Vapor Pressure (mm Hg):	Not Applicable
Vapor Density (AIR=1):	Not Applicable
Specific Gravity (Water=1):	Not Applicable
Melting Point:	Not Applicable
Evaporation Rate (Butyl Acetate=1):	Not Applicable
Solubility in Water:	Appreciable—Soluble to 10% at ambient conditions.
Appearance:	White powder interspersed with cream colored flakes.

IV. FIRE AND EXPLOSION DATA

Flash Point (Method Used):	None
Flammable Limits:	**LEL:** No Data **UEL:** No Data
Extinguishing Media:	Water, dry chemical, CO_2, foam
Special Firefighting Procedures:	Self-contained positive pressure breathing apparatus and protective clothing should be worn when fighting fires involving chemicals.
Unusual Fire and Explosion Hazards:	None

V. REACTIVITY DATA

Stability:	Stable
Hazardous Polymerization:	Will not occur
Incompatibility (Materials to Avoid):	None
Hazardous Decomposition or Byproducts:	May release CO_2 on burning

VI. HEALTH HAZARD DATA

Route(s) of Entry:	**Inhalation?** Yes **Skin?** No **Ingestion?** Yes
Health Hazards (Acute and Chronic):	Inhalation of powder may prove locally irritating to mucous membranes. Ingestion may cause discomfort and/or diarrhea. Eye contact may prove irritating.
Carcinogenicity:	**NTP?** No **IARC Monographs?** No **OSHA Regulated?** No

ALCONOX® MATERIAL SAFETY DATA SHEET (cont'd)

Signs and Symptoms of Exposure: Exposure may irritate mucous membranes. May cause sneezing.

Medical Conditions Generally Aggravated by Exposure: Not Established. Unnecessary exposure to this product or any industrial chemical should be avoided. Respiratory conditions may be aggravated by powder.

Emergency and First Aid Procedures: **Eyes**—Immediately flush eyes with water for at least 15 minutes. Call a physician.
Skin—Flush with plenty of water.
Ingestion—Drink large quantities of water or milk. Do not induce vomiting. If vomiting occurs re-administer fluids. See a physician for discomfort.

VII. PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken if Material is Released or Spilled: Material foams profusely. Recover as much as possible and flush remainder to sewer.

Waste Disposal Method: Material is biodegradable. Small quantities may be disposed of in sewer. Large quantities should be disposed of in accordance with local ordinances for detergent products.

Precautions to be Taken in Storing and Handling: Material should be stored in a dry area to prevent caking.

Other Precautions: No special requirements other than the good industrial hygiene and safety practices employed with any industrial chemical.

VIII. CONTROL MEASURES

Respiratory Protection (Specify Type): Dust mask—Recommended

Ventilation: **Local Exhaust**—Normal
Special—Not Required
Mechanical—Not Required
Other—Not Required

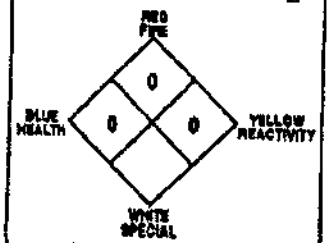
Protective Gloves: Impervious gloves are useful but not required.

Eye Protection: Goggles are recommended when handling solutions.

Other Protective Clothing or Equipment: None

Work/Hygienic Practices: No special practices required.

National Fire Protection Association 704 labeling:



Degree of Hazard:
0=insignificant
1=slight
2=moderate
3=high
4=extreme

Liqui-Nox®

Document #112

MATERIAL SAFETY DATA SHEET

I. IDENTIFICATION

Product Name (As appears on Label):	LIQUI-NOX®
CAS Registry Number:	Not Applicable
Date Prepared:	January 1, 1998
Chemical Family:	Anionic Liquid Detergent

II. HAZARDOUS INGREDIENTS/IDENTITY INFORMATION

There are no hazardous ingredients in LIQUI-NOX® as defined by the OSHA Standard and Hazardous Substance List 29 CFR 1910 Subpart Z.

III. PHYSICAL/CHEMICAL CHARACTERISTICS

Boiling Point:	214°F
Vapor Pressure (mm Hg):	No Data
Vapor Density (AIR =1):	No Data
Specific Gravity (Water=1):	1.075
Melting Point:	Not Applicable
Evaporation Rate (Butyl Acetate = 1):	Slower
Solubility in Water:	Completely soluble in all proportions.
Appearance:	Yellow liquid, nearly odorless

IV. FIRE AND EXPLOSION DATA

Flash Point:	None (Cleveland Open Cup)
Flammable Limits:	**LEL:** No Data **UEL:** No Data
Extinguishing Media:	Water, Dry Chemicals, CO_2, Foam
Special Firefighting Procedures:	Self-contained positive pressure breathing apparatus and protective clothing should be worn when fighting fires involving chemicals.
Unusual Fire and Explosion Hazards:	None.

V. REACTIVITY DATA

Stability:	Stable
Conditions To Avoid:	None
Incompatibility (Materials To Avoid):	Oxidizing agents.
Hazardous Decomposition Or Byproducts:	May release SO_2 on burning.

VI. HEALTH HAZARD DATA

Routes of Entry:	**Inhalation?** No **Skin?** Yes **Ingestion?** Yes
Health Hazards (Acute and Chronic):	Skin contact may prove locally irritating, causing drying and/or chapping. Ingestion may cause discomfort and/or diarrhea.
Carcinogenicity:	**NTP?** No **IARC Monographs?** No **OSHA Regulated?** No

Signs and Symptoms of Exposure: Prolonged skin contact may cause drying and/or chapping.

Medical Conditions Generally Aggravated by Exposure: Not established. Unnecessary exposure to this product or any industrial chemical should be avoided.

Emergency and First Aid Procedures: **Eyes**—Immediately flush with water for at least 15 minutes
Skin—Flush with plenty of water
Ingestion—Drink large quantities of water or milk. See a physician for discomfort.

VII. PRECAUTIONS FOR SAFE HANDLING AND USE

Steps to be Taken if Material is Released or Spilled: Material foams profusely. For small spills recover as much as possible with absorbent material and flush remainder to sewer. Material is biodegradable.

Waste Disposal Method: Small quantities may be disposed of in sewer. Large quantities should be disposed of in accordance with local ordinances for detergent products

Precautions to be Taken in Storing and Handling: No special precautions in storing. Use protective equipment when handling undilute material.

Other Precautions: No special requirements other than good industrial hygiene and safety practices employed with any industrial chemical.

VIII. CONTROL MEASURES

Respiratory Protection (Specify Type): Not Required
Ventilation: **Local Exhaust**—Normal
Special—Not Required
Mechanical—Not Required
Other—Not Required

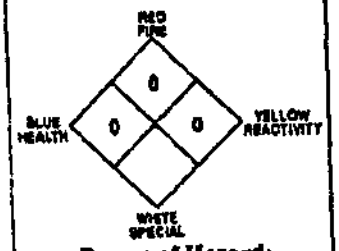
Protective Gloves: Impervious gloves are recommended.

Eye Protection: Goggles and/or splash shields are recommended.

Other Protective Clothing or Equipment: Not required

Work/Hygienic Practices: No special practices required.

National Fire Protection Association 704 labeling:



Degree of Hazard:
0=insignificant
1=slight
2=moderate
3=high
4=extreme

NITRIC ACID 1.0 N AND 2.0 N VOLUMETRIC SOLUTIONS

MSDS Number: N3659 --- *Effective Date: 11/06/97*

1. Product Identification

Synonyms: Azotic acid solution; nitric acid 6.3%; nitric acid 1.0 N volumetric solution; nitric acid 2.0 N volumetric solution; nitric acid 12.6%
CAS No.: 7697-37-2
Molecular Weight: 63.00
Chemical Formula: HNO3 in H2O
Product Codes:
J.T. Baker: 5639
Mallinckrodt: 3510

2. Composition/Information on Ingredients

Ingredient	CAS No	Percent	Hazardous
Nitric Acid	7697-37-2	6.3 - 12.	Yes
Water	7732-18-5	> 87%	No

3. Hazards Identification

Emergency Overview

POISON! DANGER! OXIDIZER. CONTACT WITH OTHER MATERIAL MAY CAUSE FIRE. CORROSIVE. LIQUID AND MIST CAUSE SEVERE BURNS TO

ALL BODY TISSUE. MAY BE FATAL IF SWALLOWED. HARMFUL IF INHALED. INHALATION MAY CAUSE LUNG AND TOOTH DAMAGE.

J.T. Baker SAF-T-DATA(tm) Ratings (Provided here for your convenience)

Health Rating: 3 - Severe (Poison)
Flammability Rating: 0 - None
Reactivity Rating: 2 - Moderate
Contact Rating: 3 - Severe (Corrosive)
Lab Protective Equip: GOGGLES & SHIELD; LAB COAT & APRON; VENT HOOD; PROPER GLOVES
Storage Color Code: White (Corrosive)

Potential Health Effects

Nitric acid is extremely hazardous; it is corrosive, reactive, an oxidizer, and a poison.

Inhalation:
Corrosive! Inhalation of vapors can cause breathing difficulties and lead to pneumonia and pulmonary edema, which may be fatal. Other symptoms may include coughing, choking, and irritation of the nose, throat, and respiratory tract.
Ingestion:
Corrosive! Swallowing nitric acid can cause immediate pain and burns of the mouth, throat, esophagus and gastrointestinal tract.
Skin Contact:
Corrosive! Can cause redness, pain, and severe skin burns. Concentrated solutions cause deep ulcers and stain skin a yellow or yellow-brown color.
Eye Contact:
Corrosive! Vapors are irritating and may cause damage to the eyes. Contact may cause severe burns and permanent eye damage.
Chronic Exposure:
Long-term exposure to concentrated vapors may cause erosion of teeth and lung damage. Long-term exposures seldom occur due to the corrosive properties of the acid.
Aggravation of Pre-existing Conditions:
Persons with pre-existing skin disorders, eye disease, or cardiopulmonary diseases may be more susceptible to the effects of this substance.

---

4. First Aid Measures

Immediate first aid treatment reduces the health effects of this substance.
Inhalation:
Remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Call a physician.

Ingestion:
DO NOT INDUCE VOMITING! Give large quantities of water or milk if available. Never give anything by mouth to an unconscious person. Get medical attention immediately.
Skin Contact:
In case of contact, immediately flush skin with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Wash clothing before reuse. Thoroughly clean shoes before reuse. Get medical attention immediately.
Eye Contact:
Immediately flush eyes with plenty of water for at least 15 minutes, lifting lower and upper eyelids occasionally. Get medical attention immediately.

5. Fire Fighting Measures

Fire:
Not combustible, but substance is a strong oxidizer and its heat of reaction with reducing agents or combustibles may cause ignition. Can react with metals to release flammable hydrogen gas.
Explosion:
May react explosively with combustible organic or readily oxidizable materials such as: alcohols, turpentine, charcoal, organic refuse, metal powder, hydrogen sulfide, etc.
Fire Extinguishing Media:
If involved in a fire, use water spray.
Special Information:
Increases the flammability of combustible, organic and readily oxidizable materials. In the event of a fire, wear full protective clothing and NIOSH-approved self-contained breathing apparatus with full facepiece operated in the pressure demand or other positive pressure mode.

6. Accidental Release Measures

Ventilate area of leak or spill. Wear appropriate personal protective equipment as specified in Section 8. Isolate hazard area. Keep unnecessary and unprotected personnel from entering. Contain and recover liquid when possible. Neutralize with alkaline material (soda ash, lime), then absorb with an inert material (e. g., vermiculite, dry sand, earth), and place in a chemical waste container. Do not use combustible materials, such as saw dust. Do not flush to sewer! US Regulations (CERCLA) require reporting spills and releases to soil, water and air in excess of reportable quantities. The toll free number for the US Coast Guard National Response Center is (800) 424-8802.

J. T. Baker NEUTRASORB(tm) or TEAM(tm) 'Low Na+' acid neutralizers are recommended for spills of this product.

7. Handling and Storage

Keep in a tightly closed container, stored in a cool, dry, ventilated area. Protect from physical damage and direct sunlight. Isolate from incompatible substances. Containers of this material may be hazardous when empty since they retain product residues (vapors, liquid); observe all warnings and precautions listed for the product.

8. Exposure Controls/Personal Protection

Airborne Exposure Limits:
For Nitric Acid:
OSHA Permissible Exposure Limit (PEL):
2 ppm (TWA)
ACGIH Threshold Limit Value (TLV):
2 ppm (TWA); 4 ppm (STEL)
Ventilation System:
A system of local and/or general exhaust is recommended to keep employee exposures below the Airborne Exposure Limits. Local exhaust ventilation is generally preferred because it can control the emissions of the contaminant at its source, preventing dispersion of it into the general work area. Please refer to the ACGIH document, *Industrial Ventilation, A Manual of Recommended Practices*, most recent edition, for details.
Personal Respirators (NIOSH Approved):
If the exposure limit is exceeded, wear a supplied air, full-facepiece respirator, airlined hood, or full-facepiece self-contained breathing apparatus. Nitric acid is an oxidizer and should not come in contact with cartridges and canisters that contain oxidizable materials, such as activated charcoal. Canister-type respirators using sorbents are ineffective.
Skin Protection:
Wear impervious protective clothing, including boots, gloves, lab coat, apron or coveralls, as appropriate, to prevent skin contact.
Eye Protection:
Use chemical safety goggles and/or a full face shield where splashing is possible. Maintain eye wash fountain and quick-drench facilities in work area.

9. Physical and Chemical Properties

Appearance:
Colorless to yellowish liquid.
Odor:
Suffocating, acrid.
Solubility:
Infinitely soluble.
Specific Gravity:
No information found.
pH:
No information found.

% Volatiles by volume @ 21C (70F):
100 (as water and acid)
Boiling Point:
No information found.
Melting Point:
No information found.
Vapor Density (Air=1):
No information found.
Vapor Pressure (mm Hg):
No information found.
Evaporation Rate (BuAc=1):
No information found.

10. Stability and Reactivity

Stability:
Stable under ordinary conditions of use and storage. Containers may burst when heated.
Hazardous Decomposition Products:
When heated to decomposition, emits toxic nitrogen oxides fumes and hydrogen nitrate.
Hazardous Polymerization:
Will not occur.
Incompatibilities:
A dangerously powerful oxidizing agent, concentrated nitric acid is incompatible with most substances, especially strong bases, metallic powders, carbides, hydrogen sulfide, turpentine, and combustible organics.
Conditions to Avoid:
Heat and incompatibles.

11. Toxicological Information

For Nitric Acid: Investigated as a mutagen and reproductive effector.

--------\Cancer Lists\----------			
	---NTP Carcinogen---		
Ingredient	Known	Anticipated	IARC Category
----------	-----	----------	----------
Nitric Acid (7697-37-2)	No	No	None
Water (7732-18-5)	No	No	None

12. Ecological Information

Environmental Fate:
No information found.
Environmental Toxicity:

No information found.

13. Disposal Considerations

Whatever cannot be saved for recovery or recycling should be managed in an appropriate and approved waste facility. Although not a listed RCRA hazardous waste, this material may exhibit one or more characteristics of a hazardous waste and require appropriate analysis to determine specific disposal requirements. Processing, use or contamination of this product may change the waste management options. State and local disposal regulations may differ from federal disposal regulations. Dispose of container and unused contents in accordance with federal, state and local requirements.

14. Transport Information

Domestic (Land, D.O.T.)

Proper Shipping Name: NITRIC ACID (WITH NOT MORE THAN 70% NITRIC ACID)
Hazard Class: 8
UN/NA: UN2031
Packing Group: II
Information reported for product/size: 20L

International (Water, I.M.O.)

Proper Shipping Name: NITRIC ACID (WITH NOT MORE THAN 70% NITRIC ACID)

SULFURIC ACID, < 10%

MSDS Number: S8236 — *Effective Date: 09/24/97*

1. Product Identification

Synonyms: Sulfuric acid solution; Sulfuric Acid Volumetric Solutions 2.0 Normal and below
CAS No.: 7664-93-9
Molecular Weight: 98.07
Chemical Formula: H2SO4 in H2O
Product Codes:
J.T. Baker: 4699, 4703, 4704, 5640, 5641, 5642, 5690, 5692, 5693, 5694
Mallinckrodt: 6843, 7610, H366, H372, H381, H389, H392, H641

2. Composition/Information on Ingredients

Ingredient	CAS No	Percent	Hazardous
Sulfuric Acid	7664-93-9	0.1 - 10%	Yes
Water	7732-18-5	90 - 99%	No

3. Hazards Identification

Emergency Overview

DANGER! CORROSIVE. LIQUID AND MIST CAUSE SEVERE BURNS TO ALL BODY TISSUE. MAY BE FATAL IF SWALLOWED OR CONTACTED WITH SKIN. HARMFUL IF INHALED. AFFECTS TEETH. CANCER HAZARD. STRONG INORGANIC ACID MISTS CONTAINING SULFURIC ACID CAN CAUSE CANCER. Risk of cancer depends on duration and level of exposure.

J.T. Baker SAF-T-DATA(tm) Ratings (Provided here for your convenience)

Health Rating: 2 - Moderate
Flammability Rating: 0 - None

Reactivity Rating: 1 - Slight
Contact Rating: 3 - Severe (Corrosive)
Lab Protective Equip: GOGGLES & SHIELD; LAB COAT & APRON; VENT HOOD; PROPER GLOVES
Storage Color Code: White (Corrosive)

Potential Health Effects

Inhalation:
Corrosive. Effects should be less severe than from exposure to higher concentrations of sulfuric acid. Symptoms may include irritation of the nose and throat, labored breathing, as well as lung edema, damage to the mucous membranes and upper respiratory tract.
Ingestion:
Corrosive. Effects should be less severe than from exposure to higher concentrations of sulfuric acid. Symptoms may include severe burns of the mouth, throat, and stomach. Circulatory collapse with clammy skin, weak and rapid pulse, shallow respirations, and scanty urine may follow ingestion or skin contact. Circulatory shock is often the immediate cause of death. May cause sore throat, vomiting, diarrhea.
Skin Contact:
Corrosive. Effects should be less severe than from exposure to higher concentrations of sulfuric acid. Symptoms may include redness, pain, and burns to the skin. Circulatory collapse with clammy skin, weak and rapid pulse, shallow respirations, and scanty urine may follow ingestion or skin contact. Circulatory shock is often the immediate cause of death.
Eye Contact:
Corrosive. Effects should be less severe than from exposure to higher concentrations of sulfuric acid. Symptoms may include blurred vision, redness, pain, and burns to eye tissue. Concentrated solutions can cause blindness.
Chronic Exposure:
Long term exposure to mist or vapors may cause damage to teeth. Chronic exposure to mists containing sulfuric acid is a cancer hazard.
Aggravation of Pre-existing Conditions:
Persons with pre-existing skin disorders or eye problems or impaired respiratory function may be more susceptible to the effects of the substance.

---

4. First Aid Measures

First aid procedures given apply to concentrated solutions. Exposures to dilute solutions may not require these extensive first aid procedures.
Inhalation:
Remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Call a physician immediately.
Ingestion:
DO NOT INDUCE VOMITING. Give large quantities of water. Never give anything by

mouth to an unconscious person. Call a physician immediately.

Skin Contact:
In case of contact, immediately flush skin with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Wash clothing before reuse. Excess acid on skin can be neutralized with a 2% solution of bicarbonate of soda. Call a physician immediately.

Eye Contact:
Immediately flush eyes with gentle but large stream of water for at least 15 minutes, lifting lower and upper eyelids occasionally. Call a physician immediately.

5. Fire Fighting Measures

Fire:
Not combustible, but substance is a strong oxidizer and its heat of reaction with reducing agents or combustibles may cause ignition.

Explosion:
Contact with most metals causes formation of flammable and explosive hydrogen gas.

Fire Extinguishing Media:
Dry chemical, foam, water or carbon dioxide. Concentrated solutions are water reactive.

Special Information:
In the event of a fire, wear full protective clothing and NIOSH-approved self-contained breathing apparatus with full facepiece operated in the pressure demand or other positive pressure mode. Structural firefighter's protective clothing is ineffective for fires involving this material. Stay away from sealed containers.

6. Accidental Release Measures

Ventilate area of leak or spill. Wear appropriate personal protective equipment as specified in Section 8. Isolate hazard area. Keep unnecessary and unprotected personnel from entering. Contain and recover liquid when possible. Neutralize with alkaline material (soda ash, lime), then absorb with an inert material (e. g., vermiculite, dry sand, earth), and place in a chemical waste container. Do not use combustible materials, such as saw dust. Do not flush to sewer! US Regulations (CERCLA) require reporting spills and releases to soil, water and air in excess of reportable quantities. The toll free number for the US Coast Guard National Response Center is (800) 424-8802.

J. T. Baker NEUTRASORB(tm) or TEAM(tm) 'Low Na+' acid neutralizers are recommended for spills of this product.

7. Handling and Storage

Store in a cool, dry, ventilated storage area with acid resistant floors and good drainage. Protect from physical damage. Keep out of direct sunlight and away from heat and incompatible materials. Do not wash out container and use it for other purposes. When

diluting, always add the acid to water; never add water to the acid. When opening metal containers, use non-sparking tools because of the possibility of hydrogen gas being present. Protect from freezing. Containers of this material may be hazardous when empty since they retain product residues (vapors, liquid); observe all warnings and precautions listed for the product.

---

8. Exposure Controls/Personal Protection

Airborne Exposure Limits:
For Sulfuric Acid:
-OSHA Permissible Exposure Limit (PEL):
1 mg/m3 (TWA).
-ACGIH Threshold Limit Value (TLV):
1 mg/m3 (TWA), 3 mg/m3 (STEL)
Ventilation System:
A system of local and/or general exhaust is recommended to keep employee exposures below the Airborne Exposure Limits. Local exhaust ventilation is generally preferred because it can control the emissions of the contaminant at its source, preventing dispersion of it into the general work area. Please refer to the ACGIH document, *Industrial Ventilation, A Manual of Recommended Practices*, most recent edition, for details.
Personal Respirators (NIOSH Approved):
If the exposure limit is exceeded, a full facepiece respirator with an acid gas cartridge and dust/mist filter may be worn up to 50 times the exposure limit, or the maximum use concentration specified by the appropriate regulatory agency or respirator supplier, whichever is lowest. For emergencies or instances where the exposure levels are not known, use a full-facepiece positive-pressure, air-supplied respirator. WARNING: Air purifying respirators do not protect workers in oxygen-deficient atmospheres.
Skin Protection:
Wear impervious protective clothing, including boots, gloves, lab coat, apron or coveralls, as appropriate, to prevent skin contact.
Eye Protection:
Use chemical safety goggles and/or a full face shield where splashing is possible. Maintain eye wash fountain and quick-drench facilities in work area.

---

9. Physical and Chemical Properties

Appearance:
Clear, colorless solution.
Odor:
Odorless.
Solubility:
Miscible in water.
Specific Gravity:
ca. 1.0 (0.1%), 1.07 (10%)

pH:
1 N solution (ca. 5% w/w) = 0.3; 0.1 N solution (ca. 0.5% w/w) = 1.2; 0.01 N solution (ca. 0.05% w/w) = 2.1.
% Volatiles by volume @ 21C (70F):
> 95
Boiling Point:
No information found.
Melting Point:
3C (100%), -32C (93%), -38C (78%), -64C (65%).
Vapor Density (Air=1):
No information found.
Vapor Pressure (mm Hg):
No information found.
Evaporation Rate (BuAc=1):
No information found.

10. Stability and Reactivity

Stability:
Stable under ordinary conditions of use and storage.
Hazardous Decomposition Products:
(The following information applies to concentrated solutions). Toxic fumes of oxides of sulfur when heated to decomposition. Will react with water or steam to produce toxic and corrosive fumes. Reacts with carbonates to generate carbon dioxide gas, and with cyanides and sulfides to form poisonous hydrogen cyanide and hydrogen sulfide respectively.
Hazardous Polymerization:
Will not occur.
Incompatibilities:
Potassium chlorate, potassium perchlorate, potassium permanganate, sodium, lithium, bases, organic material, halogens, metal acetylides, oxides and hydrides, metals (yields hydrogen gas), strong oxidizing and reducing agents and many other reactive substances.
Conditions to Avoid:
Heat, incompatibles.

11. Toxicological Information

Toxicological Data:
Oral rat LD50: 2140 mg/kg; inhalation rat LC50: 510 mg/m3/2H; standard Draize, eye rabbit, 250 ug (severe); investigated as a tumorigen, mutagen, reproductive effector.
Carcinogenicity:
Cancer Status: The International Agency for Research on Cancer (IARC) has classified "strong inorganic acid mists containing sulfuric acid" as a known human carcinogen, (IARC category 1). This classification applies only to mists containing sulfuric acid and not to sulfuric acid or sulfuric acid solutions.

Ingredient	NTP Carcinogen: Known	NTP Carcinogen: Anticipated	IARC Category
Sulfuric Acid (7664-93-9)	No	No	None
Water (7732-18-5)	No	No	None

12. Ecological Information

Environmental Fate:
When released into the soil, this material may leach into groundwater. When released into the air, this material may be removed from the atmosphere to a moderate extent by wet deposition. When released into the air, this material may be removed from the atmosphere to a moderate extent by dry deposition.
Environmental Toxicity:
LC50 Flounder 100 to 330 mg/l/48 hr aerated water/Conditions of bioassay not specified;
LC50 Shrimp 80 to 90 mg/l/48 hr aerated water /Conditions of bioassay not specified;
LC50 Prawn 42.5 ppm/48 hr salt water /Conditions of bioassay not specified.
This material may be toxic to aquatic life.

13. Disposal Considerations

Whatever cannot be saved for recovery or recycling should be handled as hazardous waste and sent to a RCRA approved incinerator or disposed in a RCRA approved waste facility. Processing, use or contamination of this product may change the waste management options. State and local disposal regulations may differ from federal disposal regulations. Dispose of container and unused contents in accordance with federal, state and local requirements.

14. Transport Information

Potential Health Effects

Inhalation:
Severe irritant. Effects from inhalation of dust or mist vary from mild irritation to serious damage of the upper respiratory tract, depending on severity of exposure. Symptoms may include sneezing, sore throat or runny nose. Severe pneumonitis may occur.

Ingestion:
Corrosive! Swallowing may cause severe burns of mouth, throat, and stomach. Severe scarring of tissue and death may result. Symptoms may include bleeding, vomiting, diarrhea, fall in blood pressure. Damage may appears days after exposure.

Skin Contact:
Corrosive! Contact with skin can cause irritation or severe burns and scarring with greater exposures.

Eye Contact:
Corrosive! Causes irritation of eyes, and with greater exposures it can cause burns that may result in permanent impairment of vision, even blindness.

Chronic Exposure:
Prolonged contact with dilute solutions or dust has a destructive effect upon tissue.

Aggravation of Pre-existing Conditions:
Persons with pre-existing skin disorders or eye problems or impaired respiratory function may be more susceptible to the effects of the substance.

4. First Aid Measures

Inhalation:
Remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Call a physician.

Ingestion:
DO NOT INDUCE VOMITING! Give large quantities of water or milk if available. Never give anything by mouth to an unconscious person. Get medical attention immediately.

Skin Contact:
Immediately flush skin with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Call a physician, immediately. Wash clothing before reuse.

Eye Contact:
Immediately flush eyes with plenty of water for at least 15 minutes, lifting lower and upper eyelids occasionally. Get medical attention immediately.

Note to Physician:
Perform endoscopy in all cases of suspected sodium hydroxide ingestion. In cases of severe esophageal corrosion, the use of therapeutic doses of steroids should be considered. General supportive measures with continual monitoring of gas exchange, acid-base balance, electrolytes, and fluid intake are also required.

5. Fire Fighting Measures

Fire:
Not considered to be a fire hazard. Hot or molten material can react violently with water. Can react with certain metals, such as aluminum, to generate flammable hydrogen gas.

Explosion:
Not considered to be an explosion hazard.

Fire Extinguishing Media:
Use any means suitable for extinguishing surrounding fire. Adding water to caustic solution generates large amounts of heat.

Special Information:
In the event of a fire, wear full protective clothing and NIOSH-approved self-contained breathing apparatus with full facepiece operated in the pressure demand or other positive pressure mode.

6. Accidental Release Measures

Ventilate area of leak or spill. Keep unnecessary and unprotected people away from area of spill. Wear appropriate personal protective equipment as specified in Section 8. Spills: Pick up and place in a suitable container for reclamation or disposal, using a method that does not generate dust. Do not flush caustic residues to the sewer. Residues from spills can be diluted with water, neutralized with dilute acid such as acetic, hydrochloric or sulfuric. Absorb neutralized caustic residue on clay, vermiculite or other inert substance and package in a suitable container for disposal. US Regulations (CERCLA) require reporting spills and releases to soil, water and air in excess of reportable quantities. The toll free number for the US Coast Guard National Response Center is (800) 424-8802.

7. Handling and Storage

Keep in a tightly closed container. Protect from physical damage. Store in a cool, dry, ventilated area away from sources of heat, moisture and incompatibilities. Always add the

caustic to water while stirring, never the reverse. Containers of this material may be hazardous when empty since they retain product residues (dust, solids); observe all warnings and precautions listed for the product. Do not store with aluminum or magnesium. Do not mix with acids or organic materials.

8. Exposure Controls/Personal Protection

Airborne Exposure Limits:
- OSHA Permissible Exposure Limit (PEL): 2 mg/m3 Ceiling - ACGIH Threshold Limit Value (TLV): 2 mg/m3 Ceiling

Ventilation System:
A system of local and/or general exhaust is recommended to keep employee exposures below the Airborne Exposure Limits. Local exhaust ventilation is generally preferred because it can control the emissions of the contaminant at its source, preventing dispersion of it into the general work area. Please refer to the ACGIH document, *Industrial Ventilation, A Manual of Recommended Practices*, most recent edition, for details.

Personal Respirators (NIOSH Approved):
If the exposure limit is exceeded, a half-face dust/mist respirator may be worn for up to ten times the exposure limit or the maximum use concentration specified by the appropriate regulatory agency or respirator supplier, whichever is lowest. A full-face piece dust/mist respirator may be worn up to 50 times the exposure limit, or the maximum use concentration specified by the appropriate regulatory agency, or respirator supplier, whichever is lowest. For emergencies or instances where the exposure levels are not known, use a full-facepiece positive-pressure, air-supplied respirator. WARNING: Air-purifying respirators do not protect workers in oxygen-deficient atmospheres.

Skin Protection:
Wear impervious protective clothing, including boots, gloves, lab coat, apron or coveralls, as appropriate, to prevent skin contact.

Eye Protection:
Use chemical safety goggles and/or a full face shield where splashing is possible. Maintain eye wash fountain and quick-drench facilities in work area.

9. Physical and Chemical Properties

Appearance:
White, deliquescent pellets.

Odor:
Odorless.

Solubility:
111 g/100 g of water.

Specific Gravity:
2.13

pH:
13 - 14 (0.5% soln.)

% Volatiles by volume @ 21C (70F):
0

Boiling Point:
1390C (2534F)

Melting Point:
318C (604F)

Vapor Density (Air=1):
> 1.0

Vapor Pressure (mm Hg):
Negligible.

Evaporation Rate (BuAc=1):
No information found.

---

10. Stability and Reactivity

Stability:
Stable under ordinary conditions of use and storage. Very hygroscopic. Can slowly pick up moisture from air and react with carbon dioxide from air to form sodium carbonate.

Hazardous Decomposition Products:
Sodium oxide. Decomposition by reaction with certain metals releases flammable and explosive hydrogen gas.

Hazardous Polymerization:
Will not occur.

Incompatibilities:
Contact with water, acids, flammable liquids, and organic halogen compounds, especially trichloroethylene, may cause fire or explosion. Contact with nitromethane and other similar nitro compounds causes formation of shock-sensitive salts. Contact with metals such as aluminum, tin, and zinc causes formation of flammable hydrogen gas.

Conditions to Avoid:

Moisture, dusting and incompatibles.

11. Toxicological Information

Irritation data: skin, rabbit: 500 mg/24H severe; eye rabbit: 50 ug/24H severe; investigated as a mutagen.

--------\Cancer Lists\----------

Ingredient	---NTP Carcinogen--- Known	Anticipated	IARC Category
Sodium Hydroxide (1310-73-2)	No	No	None

12. Ecological Information

Environmental Fate:
No information found.

Environmental Toxicity:
No information found.

13. Disposal Considerations

Whatever cannot be saved for recovery or recycling should be handled as hazardous waste and sent to a RCRA approved waste facility. Processing, use or contamination of this product may change the waste management options. State and local disposal regulations may differ from federal disposal regulations. Dispose of container and unused contents in accordance with federal, state and local requirements.

HEXANE

MSDS Number: H2381 — ***Effective Date: 12/09/96***

1. Product Identification

Synonyms: Hexanes,Normal Hexane; Hexyl Hydride
CAS No.: 110-54-3 (n-hexane)
Molecular Weight: 86.18
Chemical Formula: CH3(CH2)4CH3 n-hexane
Product Codes: 9262, 9304, 9308, N168

2. Composition/Information on Ingredients

Ingredient	CAS No	Percent	Hazardous
Hexane	110-54-3	85 > 99%	Yes
Methylcyclopentane	96-37-7	1 - 2%	Yes
Trace amount of Benzene (10 ppm)	071-43-2	*	No

3. Hazards Identification

Emergency Overview

DANGER! EXTREMELY FLAMMABLE LIQUID AND VAPOR. VAPOR MAY CAUSE FLASH FIRE. HARMFUL OR FATAL IF SWALLOWED. HARMFUL IF INHALED. CAUSES IRRITATION TO SKIN, EYES AND RESPIRATORY TRACT. AFFECTS THE CENTRAL AND PERIPHERAL NERVOUS SYSTEMS.

J.T. Baker SAF-T-DATA(tm) Ratings (Provided here for your convenience)

Health Rating: 2 - Moderate
Flammability Rating: 3 - Severe (Flammable)
Reactivity Rating: 0 - None
Contact Rating: 2 - Moderate

Lab Protective Equip: GOGGLES; LAB COAT; VENT HOOD; PROPER GLOVES; CLASS B EXTINGUISHER
Storage Color Code: Red (Flammable)

Potential Health Effects

The health hazards addressed are for the major component: n-hexane.

Inhalation:
Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Greater exposure may cause muscle weakness, numbness of the extremities, unconsciousness and death.

Ingestion:
May produce abdominal pain, nausea. Aspiration into lungs can produce severe lung damage and is a medical emergency. Other symptoms expected to parallel inhalation.

Skin Contact:
May cause redness, irritation, with dryness, cracking.

Eye Contact:
Vapors may cause irritation. Splashes may cause redness and pain.

Chronic Exposure:
Repeated or prolonged skin contact may defat the skin and produce irritation and dermatitis. Chronic inhalation may cause peripheral nerve disorders and central nervous system effects.

Aggravation of Pre-existing Conditions:
Persons with pre-existing skin disorders or eye problems or impaired respiratory function may be more susceptible to the effects of the substance. May affect the developing fetus.

---

4. First Aid Measures

Inhalation:
Remove to fresh air. If not breathing, give artificial respiration. If breathing is difficult, give oxygen. Call a physician.

Ingestion:
Aspiration hazard. If swallowed, DO NOT INDUCE VOMITING. Give large quantities of water. Never give anything by mouth to an unconscious person. Get medical attention immediately.

Skin Contact:

Remove any contaminated clothing. Wipe off excess from skin. Wash skin with soap and water for at least 15 minutes. Get medical attention if irritation develops or persists.

Eye Contact:
Immediately flush eyes with plenty of water for at least 15 minutes, lifting lower and upper eyelids occasionally. Get medical attention immediately.

Note to Physician:
BEI=2,5-hexadione in urine, sample at end of shift at workweeks end, 5 mg/g creatine. Also, measure n-hexane in expired air. Analgesics may be necessary for pain management, there is no specific antidote. Monitor arterial blood gases in cases of severe aspiration.

5. Fire Fighting Measures

Fire:
Flash point: -23C (-9F) CC Autoignition temperature: 224C (435F) Flammable limits in air % by volume: lel: 1.2; uel: 7.7 Extremely Flammable Liquid and Vapor! Vapor may cause flash fire. Dangerous fire hazard when exposed to heat or flame.

Explosion:
Above flash point, vapor-air mixtures are explosive within flammable limits noted above. Contact with oxidizing materials may cause extremely violent combustion.Explodes when mixed @ 28C with dinitrogen tetraoxide. Sensitive to static discharge.

Fire Extinguishing Media:
Dry chemical, foam or carbon dioxide. Water may be ineffective.

Special Information:
In the event of a fire, wear full protective clothing and NIOSH-approved self-contained breathing apparatus with full facepiece operated in the pressure demand or other positive pressure mode. Water spray may be used to keep fire exposed containers cool. Vapors can flow along surfaces to distant ignition source and flash back. Vapor explosion hazard exists indoors, outdoors, or in sewers.

6. Accidental Release Measures

Ventilate area of leak or spill. Remove all sources of ignition. Wear appropriate personal protective equipment as specified in Section 8. Isolate hazard area. Keep unnecessary and unprotected personnel from entering. Contain and recover liquid when possible. Use non-sparking tools and equipment. Collect liquid in an appropriate container or absorb with an inert material (e. g., vermiculite, dry sand, earth), and place in a chemical waste container. Do not use combustible materials, such as saw dust. Do not flush to sewer! If a leak or spill has not ignited, use water spray to disperse the vapors, to protect personnel attempting to stop leak, and to flush spills away from exposures. US Regulations (CERCLA) require reporting spills and releases to soil, water and air in excess of reportable quantities. The toll free number for the US Coast Guard National Response

Center is (800) 424-8802. J. T. Baker SOLUSORB(tm) solvent adsorbent is recommended for spills of this product.

7. Handling and Storage

Protect against physical damage. Store in a cool, dry well-ventilated location, away from direct sunlight and any area where the fire hazard may be acute. Store in tightly closed containers (preferably under nitrogen atmosphere). Outside or detached storage is preferred. Inside storage should be in a standard flammable liquids storage room or cabinet. Separate from oxidizing materials. Containers should be bonded and grounded for transfers to avoid static sparks. Storage and use areas should be No Smoking areas. Use non-sparking type tools and equipment. Containers of this material may be hazardous when empty since they retain product residues (vapors, liquid); observe all warnings and precautions listed for the product.

8. Exposure Controls/Personal Protection

Airborne Exposure Limits:
N-Hexane [110-54-3]: -OSHA Permissible Exposure Limit (PEL): 500 ppm (TWA) - ACGIH Threshold Limit Value (TLV): 50 ppm (TWA) other isomers of hexane -ACGIH Threshold Limit Value (TLV): 500 ppm (TWA),1000ppm (STEL)

Ventilation System:
A system of local and/or general exhaust is recommended to keep employee exposures below the Airborne Exposure Limits. Local exhaust ventilation is generally preferred because it can control the emissions of the contaminant at its source, preventing dispersion of it into the general work area. Please refer to the ACGIH document, *Industrial Ventilation, A Manual of Recommended Practices*, most recent edition, for details.

Personal Respirators (NIOSH Approved):
If the exposure limit is exceeded, wear a supplied air, full-facepiece respirator, airlined hood, or full-facepiece self-contained breathing apparatus. This substance has poor warning properties.

Skin Protection:
Wear impervious protective clothing, including boots, gloves, lab coat, apron or coveralls, as appropriate, to prevent skin contact.

Eye Protection:
Use chemical safety goggles and/or a full face shield where splashing is possible. Maintain eye wash fountain and quick-drench facilities in work area.

9. Physical and Chemical Properties

Appearance:
Clear, colorless liquid.

Odor:
Light odor.

Solubility:
Insoluble in water.

Specific Gravity:
0.66

pH:
No information found.

% Volatiles by volume @ 21C (70F):
100

Boiling Point:
ca. 68C (ca. 154F)

Melting Point:
ca. -95C (ca. -139F)

Vapor Density (Air=1):
3.0

Vapor Pressure (mm Hg):
130 @ 20C (68F)

Evaporation Rate (BuAc=1):
9

---

10. Stability and Reactivity

Stability:
Stable under ordinary conditions of use and storage. Heat will contribute to instability.

Hazardous Decomposition Products:
May produce acrid smoke and irritating fumes when heated to decomposition.

Hazardous Polymerization:
Will not occur.

Incompatibilities:
Strong oxidizers.

Conditions to Avoid:
Heat, flames, ignition sources and incompatibles.

11. Toxicological Information

N-Hexane: Oral rat LD50: 28710 mg/kg. Irritation eye rabbit: 10 mg mild. Investigated as a tumorigen, mutagen and reproductive effector.

--------\Cancer Lists\----------

Ingredient	---NTP Carcinogen--- Known	Anticipated	IARC Category
Trace amount of Benzene (10 ppm) (071-43-2)	Yes	No	1
Hexane (110-54-3)	No	No	None
Methylcyclopentane (96-37-7)	No	No	None

12. Ecological Information

Environmental Fate:
When released into the soil, this material may biodegrade to a moderate extent. When released into the soil, this material is not expected to leach into groundwater. When released into the soil, this material is expected to quickly evaporate. When released into water, this material may biodegrade to a moderate extent. When released to water, this material is expected to quickly evaporate. When released into the water, this material is expected to have a half-life between 1 and 10 days. This material has an estimated bioconcentration factor (BCF) of less than 100. This material has a log octanol-water partition coefficient of greater than 3.0. This material is not expected to significantly bioaccumulate. When released into the air, this material is expected to be readily degraded by reaction with photochemically produced hydroxyl radicals. When released into the air, this material is expected to have a half-life between 1 and 10 days.

Environmental Toxicity:
No information found.

13. Disposal Considerations

Whatever cannot be saved for recovery or recycling should be handled as hazardous waste and sent to a RCRA approved incinerator or disposed in a RCRA approved waste facility. Processing, use or contamination of this product may change the waste management options. State and local disposal regulations may differ from federal disposal regulations. Dispose of container and unused contents in accordance with federal, state and local requirements.

1.0 INTRODUCTION

In accordance with your authorization, Sub-Surface Informational Surveys, Inc. (SIS) conducted a ground penetrating radar (GPR) survey on December 3, 1999 at 214 Kent Avenue in the City of Brooklyn, NY under quotation # 1.1160.99.

1.1 Purpose and Scope

GPR investigation for the location and/or orientation of suspected underground storage tanks.

1.2 Site Conditions

Open lot with occasional brush and surface debris. Surface is partial vegetation, cobblestones and gravel.

2.0 GEOPHYSICAL SURVEY

The geophysical survey was performed by Sub-Surface Informational Surveys, Inc. A transducer operator along with a supervising GPR technician performed the survey.

2.0 Geophysical Survey Procedures

The depth of the GPR survey was set at approximately 7.2' to locate any existing UST's (or) utilities. A traverse grid with a 4.0' - 5.0' spacing was used to conduct the GPR survey. Typically a 7.0' - 10.0' spacing is sufficient to detect all large capacity UST's (1,000-gallons or greater) (*2.0' - 5.0' grid) with a high degree of certainty, but because of the relatively small size of some of the areas covered, a traverse grid with a 4.0' - 5.0' spacing was used to better define any existing UST's.

The equipment used to conduct the geophysical survey included GPR equipment which consists of an electronics unit, power supply, graphic recorder, video display unit and transmitting/receiving antenna. The equipment is known collectively as a GPR system. The transmitting/receiving antenna transmits electromagnetic signals into the subsurface and then detects, amplified and displays reflections of the signal on a graphic recorder and a video display unit. As the antenna is moved slowly across the ground surface, a radar image of the subsurface is produced. The maximum depth of penetration of the GPR signal and the resolution of the reflections are a function of the antenna frequency and the electrical properties of the subsurface. As electrical conductivity of the subsurface increases, GPR signal penetration decreases. GPR reflections are produced by spatial changes in the physical properties of the subsurface (i.e., type of material, presence of any subsurface fluid and porosity) and related changes in the electrical properties of the subsurface materials in the path of the signals. The greater the difference, the stronger the observed GPR reflection.

Characteristics that are considered in the interpretation of GPR data from a given site include the size, shape and amplitude of the reflections. Metallic UST's, utilities and conduits have electrical properties uniquely different from those of the soils in which they are buried. As a result, the GPR reflections are usually of high amplitude and have distinctive shapes. For GPR profiles oriented perpendicular to the long axis of the tank, the signature is similar to a hyperbola. The signature is also a function of the tank diameter.

2.2 Geophysical Survey Results

There were two area's surveyed. The initial survey area was off the southeast corner (rear) of the 3M tank as seen in our RAM OVERVIEW. This was a very small area between the asphalt paved access road and the large tank. There were not hyperbolic features seen in any of the enclosed data.

The second area was the large open fenced-in lot which was approximately 200' east/west by 150' north/south. The area was surveyed working in-between the high brush. We were unable to survey the extreme rear of the property between the sea-wall and the rear of the existing building foundation (leveled) due to the concentration of brush. We did however, run a ferromagnetic magnetometer in that area showing on a minimum amount of signal from surface metals. All of the flat-open area's of this lot were surveyed showing no unusual hyperbolic features which are typical of the presence of suspected underground storage tanks.

Please match the RAM numbers on the attached data to the RAM numbers noted on the RAM OVERVIEW sheet. This will give you the approximate location of each of the traverses and transects at 90 degrees included in this report.

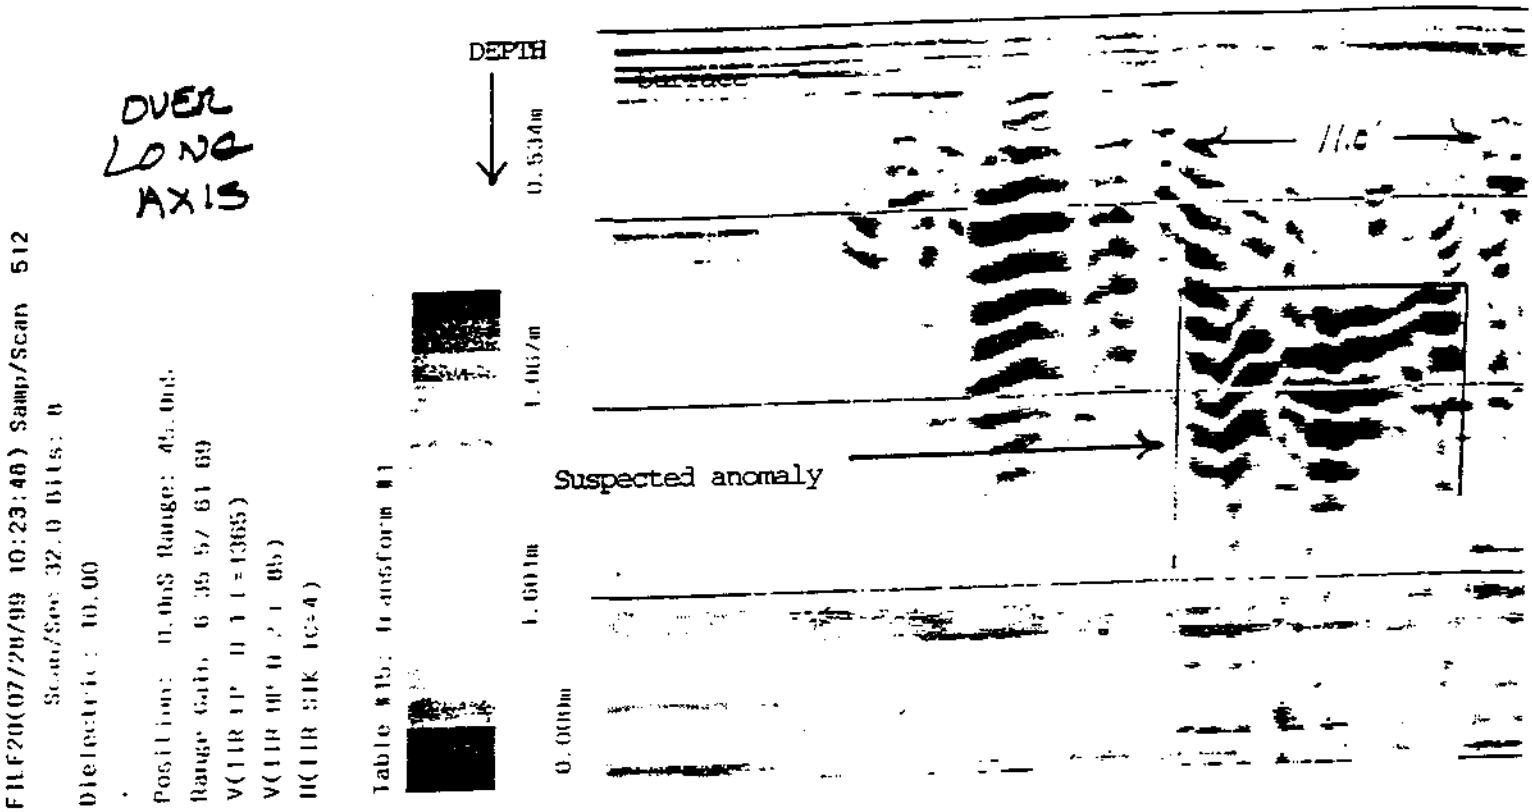
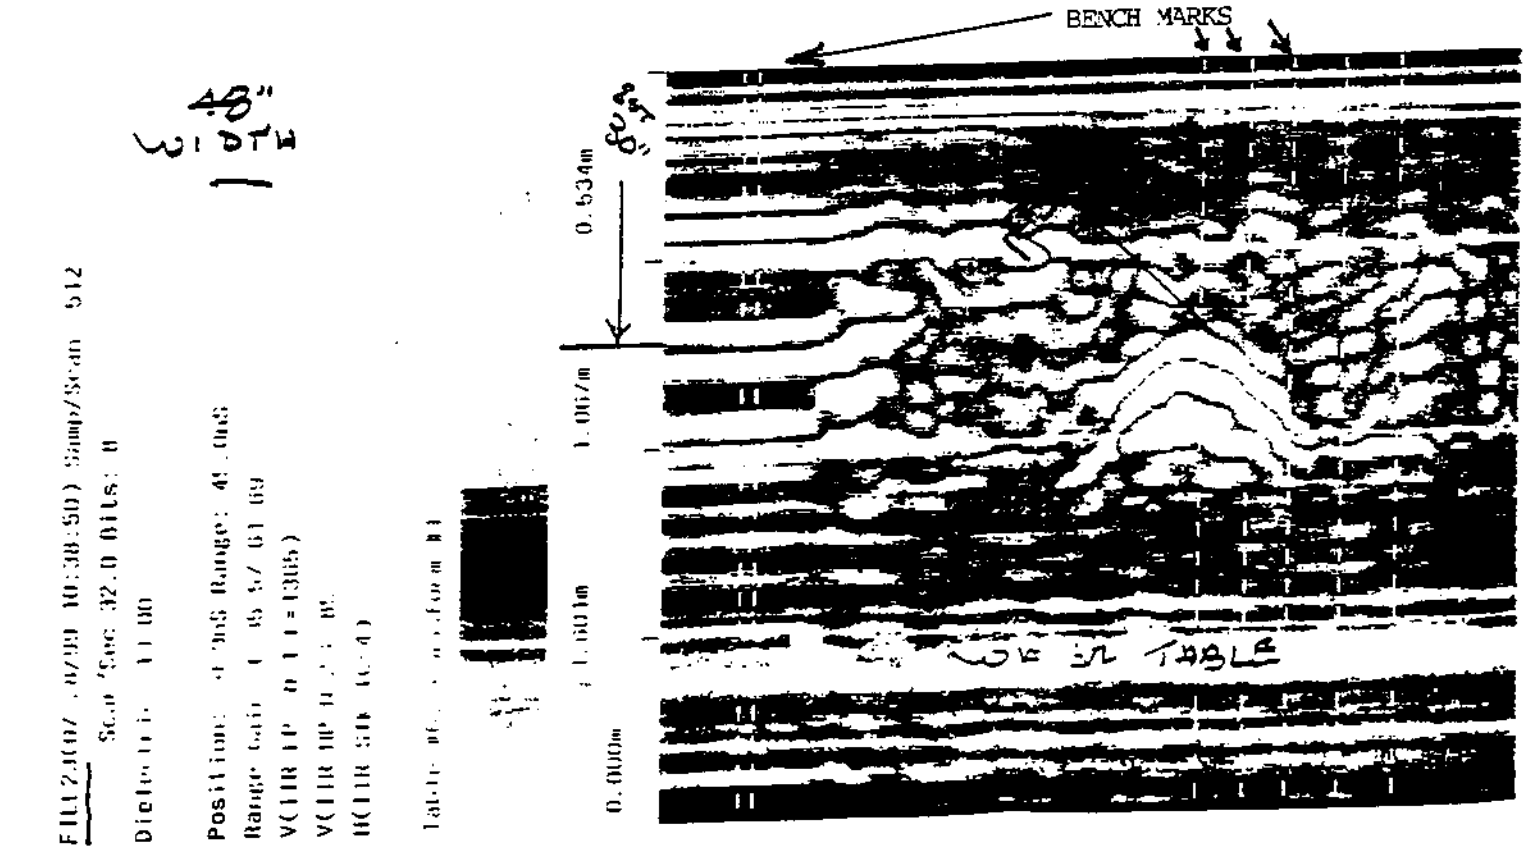
PAGE 1 OF 1

The profiles below are a sample of our field data. All files have their own "file number" with the necessary calibrated information such as dielectric constant, nanoseconds per foot, approximate depth of penetration and a horizontal scale. Vertical bench marks indicate both start and stop of the profile along with strategic information such as 180 degree direction changes and anomaly locations and approximate sizes.





4.0 PROFILE COPIES OBTAINED IN THE FIELD

The attached copies are reproductions from data acquired in the field from the SIR SYSTEM-2000 (subsurface interface radar-2000) manufactured by GSSI of N. Salem, NH. The copies in this report are exact duplicate reproductions of the originals produced by our T-104 thermal printer. Photo's (if applicable) are produced by a Sony Camcorder and computer software.

5.0 ACQUIRING PROCEDURES

The acquiring of data from the field for the location and orientation of suspected underground storage tanks, utilities or utilities within concrete slab, rebar location, grave sites and other specific anomalies has been established by the *ground penetrating radar industry* for over the past 15 years. During an investigation, a *cross-section* of the area being surveyed is permanently documented on one of the following:

1. Magnetic, cassette tape
2. MiniDisc
3. SIR-2000 hard drive
4. Profiles produced on site with a T-104 graphic printer.

We do not record every traverse since most of the information viewed on our television monitor is related to the previous traverse. Traverses (i.e. profiles) are monitored on a constant basis and when there is a significant change or a feature that might be *out of place*, this pertinent information is then recorded. This method has been an industry standard. When we are investigating for the presence of absence of utilities, it is not the practice of taking profiles of every rock, boulder, stratification line, etc., since none of these features are related to that of the utility. When there is a change or when there is suspicion of a anomaly, documentation must be made available to our customer.

During the start of all surveys, site characteristics and features must be documented to set the standard for that particular site, soil condition, conductive features, etc. While the survey is being conducted, there are periodic documentation's which are used as a permanent visual comparison to confirm the standard of that site. When a feature enters the monitor that is " out of place" as a utility, documentation at this point also must be taken. Monitor profiles that are not pertinent to that of the object we are looking for are not always documented. ALL pertinent hyperbolic features or interfacing that may be related to the utility have been documented. After the completion of our survey, it must be reasonably assured that the information is a true cross section of the project and the information obtained is accurate according to our best professional efforts.

LMS Well Sampling Logs

LMS Well Sampling Log

Date: 11/30/1999
Crew: JN,DK
Job No: 115-193
Project: North First Street
Project Site: North First Street

METERS USED

Temp.: TLC#10
pH: 98-9
Cond.: TLC#10
Turb.: NA

Well ID No.: MW-1
Well Condition: good
Well Depth/Diameter: 23 feet/ 4 inch
Well Casing Type: PVC
Screened Interval: 5 feet - 23 feet
Casing Ht./Lock No.: NA
Reference Pt.: top of PVC
Depth to Water (DTW): 8.4 feet
Water Column Ht./Vol.: 14.6 feet
Purge Est.: 54.3 gallons
Purge Method(s): 2 inch submersable
Purge Date/Time(s): 11/30/99 1527-1549

Depth(s): lowered pump as water column decreased
Rates (gpm): 2 gpm
Purged Volume: 32 gallons
DTW After Purging: purged dry @ 26 gallons
Yield Rate: L - M - H M
Purge Observations:

DTW Before Sampling:
Sample Date/Time: 11/30/99/1600
Sampling Method: disposable teflon bailer
Sampling Depth(s):
DTW After Sampling:
Chain-of-Custody No.(s):
Analytical Lab(s):
Sampling Observations:

SAMPLE CHEMISTRIES

	Temp. (°C)	pH	Sp. Cond.	Turb.
Start	17.6	7.1	2240	
End	16.6	7.1	1966	

SAMPLE ANALYSES

Parameters	Inv. No.	Pres. Meth.	Filter

PURGE CHEMISTRIES

CASE NARRATIVE

Flashpoint

Client requested flashpoint analysis on samples #3 and #4; however, proper sample containers were not provided. Client was notified and the analysis was cancelled.

8260

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

- Acetone
- 2-Butanone
- 4-Methyl,2-pentanone
- 2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

CASE NARRATIVE

8270

Samples 3 and 5
Bis(2 ethylhexyl)phthalate, a common laboratory contaminant, was found in the blank associated with these samples.

8260

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

- Acetone
- 2-Butanone
- 4-Methyl,2-pentanone
- 2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

CASE NARRATIVE

EPA8270

Samples #2-9: Bis(2-ethylhexyl)phthalate and di-n-butylphthalate, which were found in the blanks associated with these samples,are common laboratory contaminants.

8260

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

Miscellaneous
Upon final QC review, the following changes have been made:

J4678-8 m,p-xylene changed from ND to 2.1 ppb
J4678-6, 7, 8, 9 results for PCB's have been recalculated
J4678-4, 2 results for beryllium have changed
J4678-4, 9 results for cyanide have been recalculated

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

CASE NARRATIVE

TCLP8240

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

CASE NARRATIVE

EPA8270

Sample #1-13: Bis(2-ethylhexyl)phthalate and di-n-butyl phthalate, which were found in the blanks associated with these samples, are common laboratory contaminants.

8260

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

Sample J4660-6 was analyzed twice with both sets of data indicating a poor recovery of the internal standard 1,4-Dichlorobenzene-d4.

Matrix interference was proven to cause the low response of this internal standard.

Sample J4660-9 contained Isopropylbenzene and p-Ethyltoluene at concentrations slightly above the upper calibration limit. These compounds were diluted out of the required high level dilution re-analysis.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

ANALYSIS REPORT - PCB (Aroclor) by EPA8082/608

Sample: J4656-5
Client Sample ID: MW-1 Collected: 11/30/99 10.00
Matrix: Liquid Type: Grab
Remarks:

Analyzed: 12/4/99 Units: ppb

CAS No	Analyte	MDL	Concentration	Q
12674-11-2	PCB 1016	0.080	0.080	U
11104-28-2	PCB 1221	0.030	0.030	U
11141-16-5	PCB 1232	0.11	0.11	U

Case Narrative

EPA 8260:

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

Matrix spike samples J4656-2 and -3 contained Acetone and 4-Methyl-2-pentanone at concentrations above the straight analysis maximum calibration limit but below the 1:1000 dilution re-analysis recovery limit.

8270

Samples 1,2,3, and 6- Acid surrogates fail QC requirements for these samples. The samples were extracted a second time, and failed. The problem is matrix interference, likely due to high concentrations of light aromatic hydrocarbons in these samples.

Samples 2 and 3- Acid spike compounds fail for these samples. The samples were extracted a second time, and failed. The problem is matrix interference, likely due to high concentrations of light aromatic hydrocarbons in these samples.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

Mr. Ed Schwetz
Lawler, Matusky & Skully, Assoc.
1 Blue Hill Plaza
Pearl River, NY 10965

Dear Ed,

Enclosed, please find the analytical results for the following ETL Chain of Custody numbers:

COC #

J4652
J4654
J4655
J4660
J4661
J4677
J4678

Revisions have been made from the original reports. Please check each case narrative for the specific changes.

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by ETL. This program is designed to meet or exceed the requirements set by our governing agencies. Analytical work for this project met all QA/QC criteria unless otherwise stated in the remarks section of this report.

If you have any questions regarding this report package, or if I can be of further assistance, you may contact me at: 516-249-1456, extension 214.

Sincerely,
Environmental Testing Laboratories, Inc.

Patricia Werner

CASE NARRATIVE

TCLP8240

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

Sample J4652-3 and -6 were analyzed twice with both sets of data indicating a poor recovery of the internal standard 1,4-Dichlorobenzene-d4.

Sample J4652-5 was analyzed twice with both sets of data indicating a poor recovery of the internal standards Chlorobenzene-d5 and 1,4-Dichlorobenzene-d4. Matrix interference was proven to cause the low recovery of these internal standards.

8270

Sample #1,3,4,5,6 : Bis(2-ethylhexyl)phthalate, which was found in the blank associated with this sample, is a common laboratory contaminant.

Cyanide
The cyanide results were adjusted to reflect the % solids on 1/7/00.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U -The analytical result is a non-detect.

J - Indicates an estimated value. The concentration reported was detected below the Method Detection Limit.

B -The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E -The concentration of the analyte exceeded the calibration range of the instrument.

D -This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - Concentration qualifiers are as follows:

B -Entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U -Entered when the analyte was analyzed for, but not detected.

J - Indicates an estimated value. The concentration reported was detected below the Method Detection Limit.

Q - Qualifier specific entries and their meanings are as follows:

E -Reported value is estimated because of the presence of interferences.

M - Method qualifiers are as follows:

A	-	Flame AA
AS	-	Semi-automated Spectrophotometric
AV	-	Automated Cold Vapor AA
C	-	Manual Spectrophotometric
F	-	Furnace AA
NR	-	The analyte is not required to be analyzed.
P	-	ICP
T	-	Titrimetric

CASE NARRATIVE

TCLP8240/8260

The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

tclp 8270

Sample #1- Surrogates fail due to matrix interference. One of the acid surrogates is completely obscured by a non target compound.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U - The analytical result is a non-detect.

J - Indicates an estimated value. The concentration was detected lower than the Contract Required Detection Limit, but greater than the Method Detection Limit.

B - The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E - The concentration of the analyte exceeded the calibration range of the instrument.

D - This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - (Concentration) qualifiers are as follows:

B - entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U - entered when the analyte was analyzed for, but not detected.

Q - qualifier specific entries and their meanings are as follows:

E - the reported value is estimated because of the presence of interferences.

M - (Method) qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - when the analyte is not required to be analyzed.
P - ICP
T - Titrimetric

CASE NARRATIVE

8260
The following compounds were calibrated at 25, 50, 100, 150 and 200 ppb levels in the initial calibration curve:

Acetone
2-Butanone
4-Methyl,2-pentanone
2-Hexanone

M&P-Xylenes were calibrated at 10, 40, 100, 200 and 300 ppb levels.

All other compounds were calibrated at 5, 10, 20, 50, 100 and 150 ppb levels.

Samples were quantitated using the continuing calibration standard response factor as opposed to the initial calibration average response factor.

Sample J4655-3 and -7 were analyzed twice with both sets of data indicating a poor recovery of the internal standard 1,4-Dichlorobenzene-d4. Matrix interference was proven to cause the low recovery of this internal standard.

Methylene chloride, a common laboratory contaminant, was found in the blank associcated with samples 1,2,5,6,7 and 8.

8270
Bis(2-ethylhexyl)phthalate, a common laboratory contaminant, was found in the blanks associated with these samples. SBLK11 had two internal standards fail QC criteria. The extract was analyzed twice to confirm matrix interference.

Sample #2: One of the internal standards does not pass our QC requirements (response is less than 50% of the response of the internal standard in the continuing calibration standard). The sample was run a second time in order to confirm matrix interference. Compounds associated with this internal standard are benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, dibenz(a,h)anthracene, and benzo (g,h,i)perylene.

Cyanide
The results for cyanide have been calculated to include the % solids. A revised report was provided on 1/7/99.

ORGANIC METHOD QUALIFIERS

Q - Qualifier - specified entries and their meanings are as follows:

U -The analytical result is a non-detect.

J - Indicates an estimated value. The concentration reported was detected below the Method Detection Limit.

B -The analyte was found in the associated method blank as well as the sample. It indicates possible/probable blank contamination and warns the data user to take appropriate action.

E -The concentration of the analyte exceeded the calibration range of the instrument.

D -This flag identifies all compounds identified in an analysis at a secondary dilution.

INORGANIC METHOD QUALIFIERS

C - Concentration qualifiers are as follows:

B -Entered if the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL) but greater than or equal to the Instrument Detection Limit (IDL).

U -Entered when the analyte was analyzed for, but not detected.

J - Indicates an estimated value. The concentration reported was detected below the Method Detection Limit.

Q - Qualifier specific entries and their meanings are as follows:

E -Reported value is estimated because of the presence of interferences.

M - Method qualifiers are as follows:

A - Flame AA
AS - Semi-automated Spectrophotometric
AV - Automated Cold Vapor AA
C - Manual Spectrophotometric
F - Furnace AA
NR - The analyte is not required to be analyzed.
P - ICP
T - Titrimetric

Dear Gonzalez:

In accordance with our technical proposal dated May 1999, Holzmacher, McLendon & Murrell, P.C. (H2M) has completed a Phase I Environmental Site Assessment (ESA) for the site located at 214 Kent Avenue in Brooklyn, New York. Enclosed please find a copy of the final report documenting our findings. This report incorporates your comments relative to the draft Phase I ESA prepared by this office.

As outlined in Section 5.0 of the Phase I Environmental Site Assessment report, we have identified several areas of significant environmental concern associated with the subject property. Recommendations for addressing these issues are covered in Section 5.0. A proposed Phase II ESA scope of work and cost estimate are provided under a separate cover.

If you should have any questions or comments regarding this report, please do not hesitate to contact this office.

Very truly yours,

HOLZMACHER, McLENDON & MURRELL, P.C.

1.0 GENERAL INFORMATION

1.1 SCOPE

As requested by Consolidated Edison Company of New York, Inc, (Con Edison), Holzmacher, McLendon & Murrell, P.C. (H2M) conducted a Phase I Environmental Site Assessment (ESA) of the property located 214 Kent Avenue in Brooklyn, New York (hereafter termed the "subject property"). This Phase I ESA was performed in conformance with the guidelines of American Society for Testing Materials (ASTM) E 1527 - 97, "Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process" as well as Con Edison's technical specifications for Phase I Environmental Site Assessments dated March 1999. The Phase I ESA encompassed the following tasks:

1. Review of readily available Con Edison files pertaining to the subject property.
2. Review of site plans and tax map information concerning the subject property, as available.
3. Site visit, conducted on July 23, 1999, to identify and confirm existing land

use, water supply and sewage disposal, possible waste dumping areas, drainage patterns, buried and aboveground tanks, hazardous materials and petroleum usage, electrical transformers, and neighboring land uses.

4. Air monitoring and a soil gas survey with a portable photoionization detector (PID) to screen for evidence of volatile organic compounds (VOCs). Volatile organic compounds are contaminants typically associated with solvents and petroleum materials.

5. Examination of reasonably ascertainable, standard Federal and State sources to determine the environmental history of the subject property and neighboring properties within a minimum search distance of approximately one (1) mile. This task included review of historical and neighboring property information provided by Environmental Data Resources, Incorporated (EDR), an environmental database service.

6. Limited visual inspection of asbestos containing material hazards.

7. Limited visual inspection of lead-based paint hazards.

8. Review of reasonably ascertainable, standard historical sources (aerial photographs, fire insurance maps, topographic maps, etc.) as available, to determine historical land use of the subject and immediately adjacent properties.

1.2 PURPOSE

This Phase I Environmental Site Assessment has been conducted to establish the general environmental quality of the subject property and to identify actual or potential environmental liabilities.

1.3 INFORMATION SOURCES

The material summarized within this document was compiled from information found within files provided by Con Edison, Sanborn fire insurance maps, an EDR environmental data base search, a site visit and interviews with key Con Edison personnel. Con Edison

personnel that were interviewed at the North First Street Terminal and through follow-up telephone and electronic-mail conversations include the following:

- Joseph Manfre, North First Street Fuel Oil Terminal Shift Supervisor – Provided certain historical and facility operation information.
- Curt Landgrebe, Hudson Avenue Generation Station Environmental Manager – Provided certain historical and facility operation information.
- Mariela Gonzalez, Environmental Engineer – Provided certain historical information.
- Scott Marotta, Con Edison intern – Attended site visit for administrative continuity relative to Phase I ESA process.
- Margaret Karla, Con Edison intern – Attended site visit for administrative continuity relative to Phase I ESA process.

As documented herein, the above individuals have provided certain information relative to questions asked by H2M. For the purpose of this report, it is assumed that all responses were presented in good faith and were based upon that individuals best recollection.

Additional information was gathered from a review of Con Edison files which included, but were not limited to, the following documents:

- State Pollution Discharge Elimination System permit (November 1, 1997)and Best Management Plan (October 30, 1997)
- Discharge Outfall Survey and Monitoring Location Evaluation report (by Foster Wheeler Environmental Corporation)
- New York City Right-to –Know Inventory report, 1998
- Well Monitoring Data (by Miller Environmental Group)

- Part of 1992 Phase I ESA for the Pfizer property (by H2M)
- E2MIS report of spill
- SPCC Plan (March 1998 by Malcom Pirnie, Inc.)
- MPF License (June 1998)
- Groundwater Contingency Plan
- Ravenswood Generating Station Administrative Procedure Oil Storage Tank Inspection (May 2, 1997)

1.4 SITE LOCATION

The subject property is located on the east bank of the East River with approximately 816 feet of river frontage. The northern most portion of the property fronts North Third Street and the southern most portion borders Grand Street Park on Grand Street. The eastern most portion of the property fronts Kent Avenue and the postal address for the subject facility is 214 Kent Avenue in Brooklyn, New York. The subject property is shown on Kings County Tax Maps as Block 2355, Lot 1; Block 2361, Lot 1; Block 2362, Lot 3 and Block 2376, Lot 6 and the property size is 400,515 square feet (sq. ft.) (9.19 acres), 156,420 sq. ft. (3.59 acres) of which are shown on tax maps as being underwater between the bulkhead and the western most property line.

Review of a topographical survey prepared by the United States Geological Survey (USGS) indicates that the topography of the site is relatively flat with a shallow slope towards the East River and the terrain is situated at approximately 10 to 20 feet above mean sea level (msl). Based on H2M's groundwater investigation experience within the vicinity

of the subject property, groundwater is expected to be encountered at approximately 5 feet above mean sea level (msl) and regional groundwater is expected to flow to the west with tidal influences.

1.5 SITE DESCRIPTION

For the purpose of this report, the site (see Appendix D, picture No. 1) is divided into two sections, one of which is the oil transfer and storage portion (see Appendix D, picture No. 2) and the other is the former Pfizer property (see Appendix D, picture No. 3). The oil transfer and storage portion of the property contains six aboveground storage tanks, one underground storage tank, a one-story structure (see Appendix D, picture No. 4), docks and storage shed. The Pfizer portion of the property contains four aboveground storage tanks, two one-story structures, a dock and one shed.

The subject property consists of four parcels of land of which three were used for the storage and/or distribution of No. 6 fuel oil. According to Con Edison personnel, the fourth parcel has remained unused since its purchase date in 1993, with the exception of the dock area. The portion of the fourth parcel that is included in the East River is being utilized by Con Edison as dock space. According to information obtained from Con Edison files, the fourth parcel was formerly owned by Charles Pfizer and Company, Incorporated (Pfizer) and served as a transfer and storage facility for molasses and sulfuric acid. According to Con Edison personnel, Pfizer utilized the molasses and sulfuric acid in the production of cough syrup at a separate manufacturing facility, also

located in Brooklyn, New York. Information obtained from a December 1992 Phase I ESA of the Pfizer property, prepared by H2M, indicated that the transfer and storage operation ceased around July of 1984.

2.0 SITE HISTORY

In order to compile information relative to the subject site history, available fire insurance maps and aerial photographs were reviewed. In addition, Con Edison files were reviewed and key personnel were interviewed.

2.1 FIRE INSURANCE MAPS

In order to determine historical land use of the subject property, a search of historical fire insurance maps was performed. Fire insurance maps (see Appendix A) were available for the subject property for the years 1887, 1904, 1905, 1909, 1916, 1918, 1935, 1942, 1947, 1950, 1951, 1977, 1978, 1981, 1991, 1992, 1993, 1995 and 1996. The portion of the property located on Block 2376, Lot 6 was located on a separate set of fire insurance maps than Block 2355, Lot 1; Block 2361, Lot 1 and Block 2362, Lot 3, all of which were on a single map set.

The 1887 map for Block 2376, Lot 6 identified the subject parcel as containing the Nassau Ferry Company and Hardy, Voorhees and Company Lumber Yard. The Ferry Company property contained two loading ramps and a dock for the ferries, and a one-story structure identified as a waiting room. The lumberyard contained several one to

three-story structures identified as lumber sheds/storage and a sawing and planning mill. Additionally, the lumberyard contained a dock.

The 1904 fire insurance map shows the Nassau Ferry Company as remaining unchanged, however the dock is identified as containing a coal bin. The lumberyard no longer exists and a new structure has taken its place. The new structure is located at the water's edge and contains a small dock in addition to the original dock from the former lumberyard. The property also has had the shoreline altered in the form of an alcove.

The 1905 and 1909 maps show no detail for the subject property or surrounding properties. The 1918 fire insurance map shows the Nassau Ferry Company property unchanged from the 1904 map, however the former lumber property contains a two-story storage/office structure and a one-story office structure. In the 1935 map the one-story structure is no longer exists and the property is identified as being occupied by F. J. Bruce, Inc. which is a lath and lumber company. The Nassau Ferry property remained unchanged.

Charles Pfizer and Company, Inc. is identified as occupying the Nassau Ferry Company and F. J. Bruce, Inc. site in the 1947 fire insurance map. Two above ground steel constructed storage tanks with two million and three million-gallon capacities are identified on the property as containing molasses. One aboveground storage tank constructed of steel has a 100,000-gallon capacity and is identified as containing sulfuric acid. A one-story pump building, two-story vacant structure, shed and one-story dwelling

are identified on the site. Additionally, the two docks are no longer present and a concrete bulkhead is shown along the shoreline and is identified as being constructed of concrete on woodpiles.

The 1950 map shows the property unchanged from the previous mapped year and the 1977 map shows the vacant structure removed and a metal equipment shed constructed on the property. The 1981 through 1993 maps indicate the property remained the same as shown in the 1977 fire insurance map. The 1995 map shows a one-story structure constructed on the property. The property appears to remain unchanged through the 1996 fire insurance map.

Block 2361, Lot 1 is shown as containing a sugar refining company in the 1887 fire insurance map. Block 2361, Lot 1 is shown on the 1887 map as containing Hardy, Voorhees and Company Lumber Yard and Block 2362, Lot 3 contains C. W. Wilson Lumber Yard and Hardy, Voorhees and Company Lumber Yard. The sugar refining property contains several structures that appear to be interconnected and encompass the complete property. An acid storage area and melting pan room are identified in the structure. The remaining portions of the structure are primarily used for the storage of raw sugar. The Hardy, Voorhees and Company Lumber Yard at Block 2361, Lot 1 property contains several shed structures and the C. W. Wilson Lumber Yard contains a two-story structure, one-story structure and a shed. The Hardy, Voorhees and Company Lumber Yard on Block 2362, Lot 3 contains two two-story structures.

The 1905 map shows the sugar refining property as being occupied by the American Coffee Company. The former structure is shown as being renovated for use by the American Coffee Company. A structure is shown as extending over the dock and encompasses the entire dock area. Block 2361, Lot 1 is shown as containing no structures and is occupied by M. M. Miller Agent Coal Pocket and is being utilized as a storage yard. M. Samuel and Sons Metals occupies Block 2362, Lot 1 and the property contains a one-story structure and shed.

The 1909 fire insurance map show no detail for the subject property and surrounding properties when compared to the 1905 map. The M. M. Miller Agent Coal Pocket property is shown with no detail on the 1916 map. The American Coffee Company property appeared to remain structurally unchanged in the 1916 map with the exception of a change in operation. The property is being utilized by the American Sugar Refining Company for the storage of sugar. M. Samuel and Sons Metals property remains unchanged, however Thos. W. Kiley Co. has constructed a one-story structure on the adjoining lot. Thos. W. Kiley Co. property is identified on the 1916 map as being used for the storage of steel.

In the 1942 insurance map the M. M. Miller Agent Coal Pocket property is being used by the Great American Fuel Corporation, which has constructed 2 one-story structures on the property. Additionally, the property contains two coal bins and four unknown structures, which appear to resemble tanks. The M. Samuel and Sons Metal Property remains unchanged with the exception of a name change to Samuel Sons Iron

and Steel Company, Inc. Additionally, the property is identified as being utilized for a metal scrapping operation. The American Sugar Refining Company property remains unchanged with the exception that a portion of the building had been removed and a storage area is identified as stirex storage.

The 1951 map shows a garage as being constructed on the portion of the American Sugar Refining Company property where a structure had been shown as removed. Two structures suspected of being gasoline tanks are identified as well as a 38,000-gallon capacity and 45,000-gallon capacity water tank. Furthermore, the building is identified as being constructed in 1898. The Great American Fuel Corporation property is shown as only containing four unknown structures identified as concrete coal pockets on concrete piers. A paint and lacquer manufacturer occupies the Thos. W. Kiley Co. property and the Samuel Sons Iron and Steel Company, Inc. property remains the same.

The 1978 fire insurance map shows NEPCO Terminal Corporation as occupying Block 2355, Lot 1; Block 2361, Lot 1 and Block 2362, Lot 3. The properties have been cleared and Block 2355, Lot 1 contains three steel constructed aboveground storage tanks of six million-gallon, six million-gallon and 4.88 million-gallon capacity. The property in its entirety is shown as being within an earthen dike and the tanks are identified as containing No. 6 fuel oil. Block 2361, Lot 1 is similar to Block 2355, Lot 1 in that the property contains three steel constructed storage tanks, all of which are within an earthen dike at the perimeter of the property and being utilized for No. 6 fuel oil storage. Two of the tanks have a six million-gallon capacity each and the last tank has a 2.325 million-

gallon capacity. Additionally, the property contains a concrete pier on woodpiles. Block 2362, Lot 3 contains NEPCO Terminal Corporations service building and is identified as being constructed in 1965. The paint and lacquer manufacture exists unchanged. The 1981 through 1996 fire insurance maps show the subject property as unchanged.

2.2 AERIAL PHOTOGRAPHS

Aerial photographs (see Appendix B) for the subject property and surrounding areas were reviewed for the years 1954, 1975, 1984 and 1994. The 1954 aerial photograph shows the portion of the property formerly owned by Pfizer as containing present day structures including the two one story structures, two molasses tanks and sulfuric acid tank. Additional items identified in the aerial photograph include a structure on the north side of the facility in the location of an abandoned foundation observed during the site visit. The subject lot located north of the former Pfizer property appears to be vacant with the exception of four tank like structures. The subject parcel north of this parcel contains a structure or multi structures which encompass the entire block. The lot that contains the Boiler House contains a structure, which does not resemble the present day structure. In addition to the above, three docks protrude into the East River from the subject property. The surrounding properties appear to contain industrial buildings, with the exception of a residential structure to the south, which remain unchanged through the 1994 photograph.

The 1975 aerial photograph shows the former Pfizer lot as remaining unchanged

from the 1954 photograph. The two lots, which border the East River, contain the present day storage tanks, which encompass the entire lot. The present day Boiler House has been constructed and the docks have been reconstructed and remain unchanged through the 1994 photograph.

The 1984 and 1994 aerial photographs show the subject property as relatively unchanged with the exception of the removal of the structure located on the north side of the former Pfizer lot as shown in the 1984 map.

2.3 HISTORICAL SUMMARY

Based upon the information gathered from the aerial photographs, Sanborn fire insurance maps and Con Edison personnel, it is apparent that the subject property has been utilized for various operations including lumber yards, ferry docking, coal storage, sugar refining, steel storage, coffee production/distribution, molasses transfer and storage, and fuel oil transfer and storage.

According to information gathered from the Con Edison files, the property which is currently being utilized for oil transfer and storage was purchased by Con Edison in October of 1984 from NEPCO Terminal Corporation. Con Edison personnel indicated that NEPCO Utilities, Inc. opened the facility in 1965 for the transfer and storage of No. 6 fuel oil. According to Con Edison personnel, the NEPCO Utilities, Incorporated facility existed relatively similar to the current site conditions, Charter Oil operated the facility from 1980 till 1984 and North East Petroleum managed the facility for a short period of

time in 1984 prior to Con Edison's purchase. The portion of the property which is identified as the Pfizer property was purchased by Con Edison in November of 1993 from Charles Pfizer and Company, Inc. The former Pfizer property is not being utilized at this time and the oil transfer and storage portion of the property is currently being decommissioned. The aboveground storage tanks have been recently emptied and cleaned with no plans for future use.

2.4 CURRENT PROPERTY USE

The portion of the property which was formerly owned by Pfizer was utilized for the transfer and storage of molasses prior to being purchased by Con Edison. According to Con Edison personnel, Con Edison purchased the Pfizer property in 1993 and never developed or occupied the site. Since Con Edison's purchase of the Pfizer property in 1993, the property has remained relatively unchanged. The remaining portion of the Con Edison property is utilized for the transfer and storage of fuel oil. Con Edison purchased this portion of the property in 1984 for the continued use as an oil transfer and storage facility. The site has been in operation as an oil transfer and storage facility since 1965 and has remained relatively unchanged through present day.

3.0 SITE SURVEY

A H2M environmental professional (Scott Hamarich) conducted a site survey on July 23, 1999, to visually inspect the subject property and to assess the overall environmental quality. Provided below is a summary of the site survey findings.

3.1 FORMER PFIZER PROPERTY

Two molasses storage tanks (see Appendix D, picture No. 5) are located on the former Pfizer property and are of 2 million and 3 million-gallon capacity. Molasses was apparently shipped to the facility via barges. The tanks are constructed of steel and appeared to be in good shape at the time of the site inspection. According to Con Edison personnel, the tanks each contain approximately eighteen inches to two feet of molasses in them. Con Edison personnel indicated that the tanks were removed from service prior to Con Edison's purchase of the property. In addition to the 2 million and 3 million-gallon capacity tanks a molasses tank of unknown size (less than 20,000-gallon capacity) (see Appendix D, picture No. 6) is elevated above a one-story structure on the south side of the property. Con Edison personnel indicated that when this tank was in service it was utilized to fill transfer trucks with heated molasses. The tank appeared to be in good condition and was constructed of steel.

A sulfuric acid tank (see Appendix D, picture No. 7) was observed on the former Pfizer property and has a capacity of 100,000-gallons and includes a containment system (see Appendix D, picture No. 8) constructed of a concrete slab and eight foot high concrete walls. The tank is constructed of steel and appears to be in good condition. According to Con Edison personnel, the tank is empty and was removed from service prior to Con Edison's purchase of the property. The containment system is currently filled with water which according to Con Edison personnel is the result of stormwater collection.

The former Pfizer property contains two single story structures which appear to be constructed of transite panels on a steel frame and concrete slab. The western most structure was utilized to fill tanker trucks with molasses and/or sulfuric acid and contains a lead lined containment system (see Appendix D, picture No. 9). The December 1992 Phase I ESA (see Section 3.1.A) indicates the containment area was utilized to prevent migration of sulfuric acid, which may have been spilled during truck filling operations. A similar lead containment system was observed under a valve on the bulkhead.

A floor drain (see Appendix D, picture No. 10) was observed in the truck filling structure and based on visual observations, is believed to discharge to a small polyvinyl chloride collection container (see Appendix D, picture No. 11) located to the north of the structure. Piping was observed between the drainage structure and the container.

The truck filling structure contained two stainless steel tanks (see Appendix D, picture No. 12) of an unknown size and usage, along with an air compressor (see Appendix D, picture No. 9) and a hot water holding tank. No information is available pertaining to the size and former usage of the tanks.

A truck scale was observed in the other onsite structure at the former Pfizer property. This structure also contains a boiler feed pump, condensate pump and reservoir tank, unit heater, power panel, and a water treatment system. The water treatment system was apparently installed to maintain the boiler water.

The power panel included an oil filled electrical switch that may contain dielectric

fluid. It is unknown if this fluid contains polychlorinated biphenyls (PCBs). The switch appeared to be in good condition with no significant surface staining.

The structure also contained a floor drain, two floor penetrations (see Appendix D, picture Nos. 13 and 14) and a stormwater catchbasin (see Appendix D, picture No. 15). According to Con Edison personnel, the floor drain and manhole are believed to be connected to a drainage system that discharges to the East River. The December 1992 Phase I ESA indicates that stormwater catchbasins located throughout the site discharge to the East River. A floor penetration (see Appendix D, picture No. 13) was observed to be constructed as to collect liquids, however the discharge point is unknown. The second penetration is of unknown usage and has a soil bottom (see Appendix D, picture No. 14).

Located on the former Pfizer property is a chemical storage shed which, according to Con Edison personnel, was installed by Con Edison for the storage of spare boiler parts and empty 55-gallon recovery drums.

Two structural foundations were identified in the northwest corner of the property and on the north side of the property.

The former Pfizer property bulkhead is constructed of concrete on woodpiles and is in a deteriorating state.

3.1.1 December 1992 Phase I ESA Review

According to the December 1992 Phase I ESA prepared by H2M relative to the

Pfizer property, Pfizer purchased the property on June 3, 1938 from the Ireland Real Estate Company. No further information was available for the property usage prior to Pfizer's occupancy of the property, however Con Edison personnel and the Con Edison files indicate that the Pfizer property included the area to the south of the property which is now known as Grand Ferry Park. Con Edison personnel and the December 1992 Phase I ESA document indicate that the Grand Ferry Park property contained a caretaker's dwelling and a 2,000-gallon capacity underground storage tank (UST) for the Pfizer property. The storage tank is indicated to have contained fuel oil for usage in an onsite boiler. According to Con Edison personnel, the boiler produced steam required to heat the molasses prior to transfer. The December 1992 Phase I ESA indicated that the 2,000-gallon UST was abandoned in place with sand in the early 1980's. Since the 2,000-gallon tank is not within the confines of the subject property, it is not considered a significant concern.

The December 1992 Phase I ESA further indicated that a 550-gallon UST may have existed in the northern portion of the property as shown on historical maps which date back to the 1930's. No further information is available pertaining to the USTs.

The December 1992 Phase I ESA indicates that approximately 100 cubic yards of mycelium may have been buried onsite in the northeast section. Mycelium is a byproduct of fermenting citric acid, which according to the December 1992 Phase I ESA, Pfizer manufactured at an offsite manufacturing facility and may have disposed of onsite during a landfill strike. Mycelium by definition is the densely branched network of hypae

(fungal filament) in a fungus. In addition to the mycelium being disposed on the subject property, the December 1992 Phase I ESA indicates that heating coils were removed from a sulfuric acid barge and buried onsite. No further information is available pertaining to the mycelium or heating coil, however documents found within the Con Edison files indicated that soil, groundwater and sediment were sampled by Miller Environmental Group (MEG) and H2M in the early to mid 1990's.

3.1.2 Soil Sampling/Remediation

Con Edison files indicated that soil samples were collected by H2M and MEG in the early to mid 1990's and were analyzed for priority pollutant metals, total petroleum hydrocarbons, target compound list base-neutral organics, target compound list purgable organics and polychlorinated biphenyls. Sample analysis included elevated levels of volatile organic compounds resulting in the remediation of two areas at the Pfizer property. These areas included a 40-foot by 130-foot section located on the north side of the parcel in the east corner and a 40-foot by 40-foot section located in the southeast corner of the parcel. Information gathered by H2M at the time of the remediation indicated that approximately one foot of soil was removed from each location and approximately 300 tons of clean fill was backfilled into the two locations. H2M personnel who worked on the project indicated the remediation project was performed under the supervision of Con Edison and Pfizer and neither party required endpoint samples to confirm the effectiveness of the remediation effort. However, H2M personnel indicated that the soil at the remediation extent appeared to be visually clean with no

unusual coloring or objectionable odors.

3.2 OIL TRANSFER AND STORAGE FACILITY

The oil transfer and storage portion of the subject property contains six aboveground oil storage tanks and associated secondary containment (see Appendix D, picture Nos. 16 and 17), a boiler house, various storage trailers and an underground storage tank.

3.2.1 Underground Storage Tanks

According to Con Edison personnel, an underground storage tank (UST) located at the facility contains No. 6 fuel oil for usage in the Boiler House's three boilers. Con Edison personnel indicated that the UST has a 10,000-gallon capacity tank and is located under Con Edison's asphalt paved parking area and is constructed of a single layer of steel with a cathodic protection system. It was indicated that the tank also contains a high level alarm, product level gauge and automatic shut-off valve. Information gathered from Con Edison's files indicated that the facility conducts annual tightness testing. According to on Edison personnel, the tank has consistently passed the tank tightness testing criteria and the last recorded testing date was August 1998.

3.2.2 Aboveground Storage Tanks

The subject facility includes two sets of three aboveground storage tanks, with each set situated in a separate containment system. Both containment systems are

situated so as to completely surround the tanks within. The containment system in the center parcel of the subject property contains tanks No. 100, 200 and 300. The tanks are labeled as having design capacities of 142,105.64 barrels, 55,313.19 barrels and 142,673.39 barrels, respectively. Tanks No. 400, 500 and 600 have design capacities of 142,595.99 barrels, 142,858.80 barrels and 116,508.70 barrels, respectively. The tanks and containment system are constructed of steel and according to Con Edison personnel, are constructed on a 14-inch thick concrete pad. Con Edison personnel indicated the tanks have high and low level alarms that are connected to a control board in the control room of the Boiler House and a control station located on the docks. The dock side control station is utilized during the unloading of oil tankers. According to Con Edison personnel, as of July 22, 1999 the six storage tanks have been certified as gas free and are out-of-service.

3.2.3 Boiler House

The Boiler House contains three boilers, which according to Con Edison personnel, create steam for use in piping and heat exchangers (see Appendix D, picture Nos. 18 and 19) that heat the No. 6 fuel oil from the six storage tanks. Heating of the No. 6 oil is performed to make it less viscous for pumping to the Ravenswood Station. According Con Edison personnel, fuel oil is no longer pumped to the Ravenswood Station and Con Edison is in the process of permanently closing the fuel oil lines. Included in the Boiler House was a diesel powered emergency backup generator, including a 234-gallon capacity fuel storage tank. Other items in the Boiler House include air compressors,

pumps and a boiler water treatment system. The boilers are currently shutdown and are no longer being used. When the boilers were in operation, the treatment system maintained the boiler systems water quality by automatically adding Ashland Chemical Company's DWS 1807 Oxygen Scavenger, DWS 1891 Corrosion Inhibitor, Adjunct H Liquid Corrosion Inhibitor and Advantage Plus 6445 Deposit Inhibitor from 55-gallon drums. According to Con Edison personnel, the boilers are currently shutdown with no plans for future use. A chemical storage cabinet located in the Boiler House contains 5-gallon and 1-gallon containers of epoxy paint.

A fire suppression room located within the Boiler House contains a 3,000-gallon capacity tank that is labeled as containing 3% Foamite (Ethylene Glycol) in addition to approximately 55 5-gallon containers of Foamite. According to Con Edison personnel, the 3% Foamite was used in a fire suppression system for the storage tanks. The room also contains pumps for mixing the Foamite with water and discharging the product in the event of a fire. The diesel generator located in the room mixes the Foamite and water in the event of a power failure. Con Edison personnel indicated that a water tank located on the roof of the structure is connected to the fire suppression system for use as an emergency water supply. According to Con Edison personnel, carbon dioxide tanks located in the room are utilized for fire suppression in the facility's underground electrical vaults for the facility.

The Boiler House also contains a transformer room that, according to Con Edison personnel, does not contain any oil filled transformers.

3.2.4 Groundwater Monitoring

According to Con Edison personnel, Miller Environmental Group monitors groundwater at the facility on a monthly basis in accordance with the facilities Major Oil Storage Facility license. Monitoring wells were observed at the west end of North First Street, Metropolitan Avenue and North Third Street, and east of tank No. 300 (see Figure 3). These wells were installed, according to an April 25, 1994 memo prepared by Harry Coates of Con Edison, to comply with the terms of the facilities Major Oil Storage Facility license and must be visually monitored for free product. Information found within the Con Edison files, including monthly monitoring reports, indicates that no free product or odors were observed from the time the first visual monitoring through January of 1999. The results of the groundwater monitoring activity are submitted to the New York State Department of Environmental Conservation on an annual basis.

3.2.5 Miscellaneous Items

The property maintains three docks (see Appendix D, pictures No. 20, 21 and 22) for the unloading of oil tankers. The middle dock contains the piping for the ship unloading, a control room for the monitoring of the unloading event and a spill containment trailer. The spill containment trailer contains items that would be required in the event of a fuel spill (i.e. oil boom, absorbent rags, etc.). Two spill containment trailers were observed by the aboveground No. 6 fuel storage tanks and in the Boiler House's parking area. Additional trailers observed at the facility include a fire fighting

equipment storage trailer and tool trailer, both located by the No. 6 storage tanks, a spill containment trailer located on North Third Street and a miscellaneous storage trailer. The parking area of the Boiler House contains a chemical storage shed, which includes within it, two empty 55-gallon drums, three containers of diesel fuel, a container of tar and a container of grease.

No oil filled transformers were noted on the subject property. Con Edison personnel and available documents, including the facility SPCC Plan, confirmed the absence of oil filled transformers.

3.3 ASBESTOS CONTAINING MATERIAL

Suspect asbestos containing material was identified during the site visit. The suspect asbestos containing material included pipe insulation, mudded joint plaster, wall plaster, fire brick, boiler gasket material, vinyl floor tiles, floor tile mastic, roofing material, transite panels, electrical wire wrap, and window caulk. The suspect materials observed were generally in good condition.

3.4 LEAD-BASED PAINT INSPECTION

Based on the age of the structure, all painted surfaces within the facility are suspected to contain lead. All painted surfaces appeared to be in good condition.

3.5 PHOTOIONIZATION DETECTOR (PID) SURVEY

Air monitoring was conducted as part of the site investigation using a portable

photoionization detector (PID). The PID is designed to detect a wide variety of non-methane organic compounds and is used to identify areas of possible environmental concern. The PID is not designed to detect possible inorganic contaminants (i.e., metals). Organic contaminants detected by the PID are expressed in the form of total organic compounds in parts per million (ppm) equivalence units referenced to the PID's calibration gas.

Ambient air within the property boundaries ranged from 0.0 to 0.2 ppm. Readings in this range are typical of "normal" ambient air. Soil gas readings were collected at twenty-seven (27) locations throughout of the subject property. The readings were obtained by inserting the PID's probe into 1/4-inch diameter holes driven through non-paved areas to a depth of 1-2 feet below grade. All PID readings were in the range of 0.0 to 0.2 ppm, which is indicative of "normal" soil gas readings.

4.0 REGULATORY AGENCY FILE REVIEW

Regulatory agency files review was conducted through use of an environmental database service (Environmental Data Resources, Inc.) which performed a review of reasonably ascertainable, standard Federal and State environmental information sources. A complete copy of the Environmental Data Resources, Inc. (EDR) report is provided in Appendix C. The sources reviewed by EDR included but were not limited to the following lists and databases:

- New York State Inactive Hazardous Waste Disposal Sites

- New York State Leaking Underground Storage Tank Incident Reports
- New York State Solid Waste Facility/Landfill Site Registry
- New York State Petroleum Bulk Storage Facilities
- New York State Chemical Bulk Storage Facilities
- New York State Major Oil Storage Facilities
- National Priority List for Federal Superfund Cleanup (NPL)
- Federal Emergency Response Notifications System Spills (ERNS)
- Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS)

A summary of the findings of the EDR report is provided below.

4.1 SUBJECT PROPERTY

The subject property is listed on eight of the databases searched under the EDR report. The subject property was listed on the following databases: Leaking Underground Storage Tank (LUST), Resource Conservation and Recovery Information System (RCRIS) Large Quantity Generator (LQG), Emergency Response Notification System (ERNS), Facility Index System/Facility Identification Initiative Program Summary Report (FINDS), NY Spills, Chemical Bulk Storage Facilities (CBS) Aboveground Storage Tank (AST), Major Oil Storage Facility (MOSF) UST and MOSF Aboveground Storage Tank (AST).

Under the EDR searches (NY Spills and LUST) the subject property is identified as having nine spills. Of the nine spills, three were reported as being closed. The remaining six are identified as having the spill closure date listed as "not reported". Of these spills, three are reported to have occurred in containment areas and all nine were

identified as being cleaned-up. Therefore, the listed spills are not considered a significant environmental concern.

The subject property is listed as being a RCRIS LQG for 1980 and 1990. No violations were identified for these two listings. Additionally, the subject property is listed three times as being on the ERNS list.

EDR lists the subject property as containing an underground storage tank with a 10,000 gallons capacity containing No. 5 or 6 fuel oil. Seven aboveground storage tanks are listed on the subject property. Of the seven tanks, six contain No. 5 or 6 fuel oil and last, a 3,000-gallon capacity tank, contains ethylene glycol. All tanks are reported to be constructed of steel and the fuel tanks were indicated as having capacities of six million, six million, six million, six million, 4.88 million and 2.325 million gallons.

4.2 NEIGHBORING SITES

The subject property is comprised of four separate parcels. Three of the parcels, Block 2355, Lot1: Block 2361, Lot 1 and Block 2376, Lot 6, are bordered on the west by the East River and east by River Street. The property at Block 2355, Lot 1 is bordered to the north by North Third Street and south by Metropolitan Avenue. Block 2361, Lot 1 is bordered to the north by Metropolitan Avenue and south by North First Street. Block 2376, Lot 6 is bordered to the north by North First Street and south by Grand Street Park. Block 2362, Lot 3 is bordered to the west by River Street, east by Kent Avenue, north by Metropolitan Street and south by a paint and lacquer manufacturer.

The normal operating activities conducted by the neighboring occupants are examined to determine whether the subject property could potentially be impacted. The businesses surrounding the subject property include Domino Sugar, Flynn Paint, barrel refurbishers, Gleam Industries, York Display Finishing Company, Inc., and a multipurpose structure.

The EDR report lists four Coal Gas sites, one State Hazardous Waste site and one Corrective Action Report site (CORRACTS) within a 1 mile radius of the subject property. EDR list eleven LUSTs, two Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS) sites and one RCRIS Transfer, Storage and Disposal (TSD) facility within a half-mile of the subject property. The EDR report identifies ten RCRIS Small Quantity Generators (SQG), nine USTs, six RCRIS LQGs, two CBS USTs and two CBS ASTs within a one-quarter mile radius of the subject property.

Sites listed under the Coal Gas database are former gas holder sites which are all greater than one-quarter mile form the subject property and therefore not considered significant relative to the subject property.

The site identified by EDR as a State Hazardous Waste site is identified as BGE/Ansbacher Color and Dye Company. A phase I ESA and Phase II ESA were performed in the area and identified arsenic and lead contaminated soil. The report identifies the contaminated soil as not presenting a significant threat to the public or the

environment. The site is greater than one-half mile east of the subject property. This site does not present any direct environmental concerns relative to the subject property, however, local groundwater quality, including that which underlies the subject property, may have been impacted.

The site identified by EDR as a CORRACTs site has had seventeen violations, which are mainly in the compliance evaluation inspection category. The site is greater than one-eighth mile from the subject property and activities at the site should not have an impact on the subject property.

EDR lists eleven LUST sites of which all were identified as having the spills closed, the remaining releases were labeled as the spill closure date "not reported", however remedial action was indicated as being taken at each site.

The sites listed on the CERCLIS sites database lists the sites as being cleaned up, therefore the sites are not considered significant relative to the subject property.

The site identified by EDR as a RCRIS TSD facility is identified as accepting waste from off-site and has violations that are mainly within the compliance evaluation inspection category. Since the property is greater than one-eighth mile form the subject property, the site is not expected to have an impact on the subject property.

The sites listed as RCRIS SQG are all greater than one-eighth mile form the subject property and therefore not considered significant relative to the subject property.

The sites identified by EDR as containing registered USTs, CBS USTs and CBS ASTs are not expected to have an impact on the subject property, since the databases only list registered tanks.

The sites listed as RCRIS LQG are all listed as not having violations and therefore are not considered significant relative to the subject property.

5.0 CONCLUSIONS AND RECOMMENDATIONS

Based upon the scope of services outlined in Section 1.1 of this Phase I Environmental Site Assessment Report, H2M has identified several areas of significant environmental concern relative to the subject property as follows:

- A December 1992 Phase I Environmental Site Assessment performed for the former Pfizer property indicates mycelium and a sulfuric acid heating coil may have been disposed on site. Documents found within the Con Edison files indicate that soil at the property was remediated, however, no confirmatory endpoint sample analysis was conducted. An investigation of the potential environmental concerns relative to mycelium should be conducted and the effectiveness of the soil remediation efforts should be confirmed by sampling and analyzing subsurface soils.

- The December 1992 Phase I Environmental Site Assessment identified a 550-gallon UST as possibly being located in the northern portion of the former

Pfizer property. The existence of this UST should be investigated as well as any potential contamination from same.

- The two elevated stainless steel tanks should be further investigated to determine if the contents are such that the residual material could present an environmental concern.

- Suspected asbestos and lead containing paint materials were noted at the property as being in good condition and therefore do not currently present a significant environmental concern. However, any construction and/or remediation activity on-site should take into account the potential hazards associated with handling these materials.

- The floor penetrations in the south structure at the former Pfizer property should be further investigated to determine if they discharge on-site. Soils/sediments should be sampled from on-site discharge areas to determine if any contamination exists. Any contaminated soils/sediment should then be remediated.

- Containers of toxic or hazardous materials such as diesel fuel, foamite, tar, grease, etc. should be properly disposed of off-site. Residual toxic or hazardous material in storage tanks such as ethylene glycol and petroleum products as well as abandoned items such as lead containment area liners should be properly disposed of off-site. In addition, it should be verified that

all tanks are properly cleaned and closed.

- Considering the long-term industrial nature of the site, various operations that are no longer in existence and are not readily apparent could have caused or contributed to local areas of contamination. As such, it is recommended that local groundwater quality be investigated hydraulically upgradient and down gradient of the site to determine if any on-site sources of contamination are affecting groundwater quality. The existing monitoring wells could be utilized to investigate a portion of the property. An investigation of the former Pfizer property may require installation of new monitoring wells or temporary well points.

  In addition, it is recommended that soil samples be collected from shallow (0' – 2' below grade) depths in accessible areas of the site to check for local areas of contamination.

Following completion of Phase II Environmental Site Assessment activities addressing the issues identified above, environmental cleanup activities should be conducted to remediate any contaminated areas.

We certify that this is a true and accurate representation of our findings regarding the subject property.

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc. (EDR). The report meets the government records search requirements of ASTM Standard Practice for Environmental Site Assessments, E 1527-97. Search distances are per ASTM standard or custom distances requested by the user.

The address of the subject property for which the search was intended is:

NORTH 1ST ST OIL TERMINAL
BROOKLYN, NY 11211

No mapped sites were found in EDR's search of available ("reasonably ascertainable ") government records either on the subject property or within the ASTM E 1527-97 search radius around the subject property for the following Databases:

NPL:	National Priority List
Delisted NPL:	NPL Deletions
CERC-NFRAP:	Comprehensive Environmental Response, Compensation, and Liability Information System
SWF/LF:	Facility Register
AST:	Petroleum Bulk Storage (AST)
RAATS:	RCRA Administrative Action Tracking System
HMIRS:	Hazardous Materials Information Reporting System
PADS:	PCB Activity Database System
TRIS:	Toxic Chemical Release Inventory System
NPL Lien:	NPL Liens
TSCA:	Toxic Substances Control Act
MLTS:	Material Licensing Tracking System
HSWDS:	Hazardous Substance Waste Disposal Site Inventory
VCP:	Voluntary Cleanup Agreement
ROD:	ROD
CONSENT:	Superfund (CERCLA) Consent Decrees
MINES:	Mines Master Index File

Unmapped (orphan) sites are not considered in the foregoing analysis.

Search Results:

Search results for the subject property and the search radius, are listed below:

Subject Property:

The subject property was identified in the following government records. For more information on this property see page 9 of the attached EDR Radius Map report:

EXECUTIVE SUMMARY

Surrounding Properties:

Elevations have been determined from the USGS 1 degree Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified. EDR's definition of a site with an elevation equal to the subject property includes a tolerance of -10 feet. Sites with an elevation equal to or higher than the subject property have been differentiated below from sites with an elevation lower than the subject property (by more than 10 feet). Page numbers and map identification numbers refer to the EDR Radius Map report where detailed data on individual sites can be reviewed.

Sites listed in ***bold italics*** are in multiple databases.

RCRIS: The Resource Conservation and Recovery Act database includes selected information on sites that generate, store, treat, or dispose of hazardous waste as defined by the Act. The source of this database is the U.S. EPA.

A review of the RCRIS-TSD list, as provided by EDR, and dated 04/26/1999 has revealed that there is 1 RCRIS-TSD site within approximately 0.5 miles of the subject property.

Equal/Higher Elevation	Address	Dist / Dir	Map ID	Page
RADIAC RESEARCH CORP	***33 S FIRST ST***	***1/8 - 1/4 S***	***H29***	***46***

SHWS: The State Hazardous Waste Sites records are the states' equivalent to CERCLIS. These sites may or may not already be listed on the federal CERCLIS list. Priority sites planned for cleanup using state funds (state equivalent of Superfund) are identified along with sites where cleanup will be paid for by potentially responsible parties. The data come from the Department of Environmental Conservation's Inactive Hazardous waste Disposal Sites in New York State.

A review of the SHWS list, as provided by EDR, has revealed that there is 1 SHWS site within approximately 1 mile of the subject property.

Equal/Higher Elevation	Address	Dist / Dir	Map ID	Page
BQE/ANSBACHER COLOR & DYE FACT	MEEKER AVENUE	1/2 - 1 E	59	75

CERCLIS: The Comprehensive Environmental Response, Compensation and Liability Information System contains data on potentially hazardous waste sites that have been reported to the USEPA by states, municipalities, private companies and private persons, pursuant to Section 103 of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA).
CERCLIS contains sites which are either proposed to or on the National Priorities List (NPL) and sites which are in the screening and assessment phase for possible inclusion on the NPL.

A review of the CERCLIS list, as provided by EDR, and dated 04/21/1999 has revealed that there are 2 CERCLIS sites within approximately 0.5 miles of the subject property.

EXECUTIVE SUMMARY

CORRACTS: CORRACTS is a list of handlers with RCRA Corrective Action Activity. This report shows which nationally-defined corrective action core events have occurred for every handler that has had corrective action activity.

A review of the CORRACTS list, as provided by EDR, and dated 03/01/1999 has revealed that there is 1 CORRACTS site within approximately 1 mile of the subject property.

LUST: The Leaking Underground Storage Tank Incident Reports contain an inventory of reported leaking underground storage tank incidents. The data come from the Department of Environmental Conservation's Spills Information Database.

A review of the LUST list, as provided by EDR, and dated 01/01/1999 has revealed that there are 11 LUST sites within approximately 0.5 miles of the subject property.

UST: The Underground Storage Tank database contains registered USTs. USTs are regulated under Subtitle I of the Resource Conservation and Recovery Act (RCRA). The data come from the Department of Environmental Conservation's Petroleum Bulk Storage (PBS) Database

A review of the UST list, as provided by EDR, and dated 01/01/1999 has revealed that there are 9 UST sites within approximately 0.25 miles of the subject property.

CBS UST: Chemical Bulk Storage Database. Registration data collected as required by 6 NYCRR Part 596. It includes facilities storing hazardous substances listed in 6 NYCRR Part 597, in aboveground tanks with capacities of 185 gallons or greater, and/or in underground tanks of any size. Includes facilities registered (and closed) since effective date of CBS regulations (July 15, 1988) through the date request is processed.

A review of the CBS UST list, as provided by EDR, and dated 01/01/1999 has revealed that there are 3 CBS UST sites within approximately 0.25 miles of the subject property.

GROUNDWATER FLOW INFORMATION

Groundwater flow direction for a particular site is best determined by a qualified environmental professional using site-specific well data. If such data is not reasonably ascertainable, it may be necessary to rely on other sources of information, including well data collected on nearby properties, regional groundwater flow information (from deep aquifers), or surface topography.‡

BQE/ANSBACHER COLOR & DYE FACTORY (Continued) **S100115800**

Legal Action Type: Not reported
Remedial Action: Complete
Nature of Action: IRM-soil removal.
Enforcement Status. Not reported
Hazardous Waste:

arsenic (D004 Waste) - unknown
lead (D008 Waste) - unknown

Site Description:

Most of this site lies underneath the elevated BQE along Meeker Avenue between North 6th Street and North 7th Street, and between North 7th Street and North 8th Streets. It is believed that waste material and debris from the former Ansbacher Color &Dye Factory may have been used as fill material in the project area. Analytical data from the Phase I Investigation revealed Extraction Procedure Toxicity (EPTOX) for arsenic and lead. A Phase II type investigation was conducted by the New York StateDepartment of Transportation in 1988. Reconstruction of the BQE and soil removal in the "foot print" of the former color and dye facility as an Interim Remedial Measure (IRM) is complete. All of the remaining contaminated soil is covered by approximately two foot layers of asphalt and concrete. There is no significant threat from any remaining contaminated soil.

Assessment of Environmental Problems:

The contaminated soil is covered by existing layers of asphalt and concrete.

Assessment of Health Problems:

Contaminated soil was removed from the site; soil with residual arsenic and lead contamination is covered with several layers of concrete and asphalt. There are no known exposure pathways.

EPA Waste Codes Addendum

Code	Description
D001	IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.
D002	A WASTE WHICH HAS A PH OF LESS THAN 2 OR GREATER THAN 12.5 IS CONSIDERED TO BE A CORROSIVE HAZARDOUS WASTE. SODIUM HYDROXIDE, A CAUSTIC SOLUTION WITH A HIGH PH, IS OFTEN USED BY INDUSTRIES TO CLEAN OR DEGREASE PARTS. HYDROCHLORIC ACID, A SOLUTION WITH A LOW PH, IS USED BY MANY INDUSTRIES TO CLEAN METAL PARTS PRIOR TO PAINTING. WHEN THESE CAUSTIC OR ACID SOLUTIONS BECOME CONTAMINATED AND MUST BE DISPOSED, THE WASTE WOULD BE A CORROSIVE HAZARDOUS WASTE.
D003	A MATERIAL IS CONSIDERED TO BE A REACTIVE HAZARDOUS WASTE IF IT IS NORMALLY UNSTABLE, REACTS VIOLENTLY WITH WATER, GENERATES TOXIC GASES WHEN EXPOSED TO WATER OR CORROSIVE MATERIALS, OR IF IT IS CAPABLE OF DETONATION OR EXPLOSION WHEN EXPOSED TO HEAT OR A FLAME. ONE EXAMPLE OF SUCH WASTE WOULD BY WASTE GUNPOWDER.
D006	CADMIUM
D007	CHROMIUM
D008	LEAD
D009	MERCURY
D011	SILVER
D018	BENZENE
D019	CARBON TETRACHLORIDE
D022	CHLOROFORM

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

To maintain currency of the following federal and state databases, EDR contacts the appropriate governmental agency on a monthly or quarterly basis, as required.

Elapsed ASTM days: Provides confirmation that this EDR report meets or exceeds the 90-day updating requirement of the ASTM standard.

FEDERAL ASTM RECORDS:

CERCLIS: Comprehensive Environmental Response, Compensation, and Liability Information System
Source: EPA
Telephone: 703-413-0223
CERCLIS contains data on potentially hazardous waste sites that have been reported to the USEPA by states, municipalities, private companies and private persons, pursuant to Section 103 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). CERCLIS contains sites which are either proposed to or on the National Priorities List (NPL) and sites which are in the screening and assessment phase for possible inclusion on the NPL.

Date of Government Version: 04/21/99
Date Made Active at EDR: 06/09/99
Database Release Frequency: Quarterly
Date of Data Arrival at EDR: 05/14/99
Elapsed ASTM days: 26
Date of Last EDR Contact: 03/03/99

ERNS: Emergency Response Notification System
Source: EPA/NTIS
Telephone: 202-260-2342
Emergency Response Notification System. ERNS records and stores information on reported releases of oil and hazardous substances.

Date of Government Version: 12/31/98
Date Made Active at EDR: 01/18/99
Database Release Frequency: Quarterly
Date of Data Arrival at EDR: 01/13/99
Elapsed ASTM days: 5
Date of Last EDR Contact: 01/04/99

NPL: National Priority List
Source: EPA
Telephone: N/A
National Priorities List (Superfund). The NPL is a subset of CERCLIS and identifies over 1,200 sites for priority cleanup under the Superfund Program. NPL sites may encompass relatively large areas. As such, EDR provides polygon coverage for over 1,000 NPL site boundaries produced by EPA's Environmental Photographic Interpretation Center (EPIC).

Date of Government Version: 05/10/99
Date Made Active at EDR: 06/09/99
Database Release Frequency: Semi-Annually
Date of Data Arrival at EDR: 05/12/99
Elapsed ASTM days: 28
Date of Last EDR Contact: 02/08/99

RCRIS: Resource Conservation and Recovery Information System
Source: EPA/NTIS
Telephone: 800-424-9346
Resource Conservation and Recovery Information System. RCRIS includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA).

Date of Government Version: 04/26/99
Date Made Active at EDR: 06/09/99
Database Release Frequency: Semi-Annually
Date of Data Arrival at EDR: 05/14/99
Elapsed ASTM days: 26
Date of Last EDR Contact: 03/31/99

CORRACTS: Corrective Action Report
Source: EPA
Telephone: 800-424-9346
CORRACTS identifies hazardous waste handlers with RCRA corrective action activity.

Date of Government Version: 03/01/99
Date Made Active at EDR: 04/16/99
Database Release Frequency: Semi-Annually
Date of Data Arrival at EDR: 03/17/99
Elapsed ASTM days: 30

FEDERAL NON-ASTM RECORDS:

BRS: Biennial Reporting System
Source: EPA/NTIS
Telephone: 800-424-9346
The Biennial Reporting System is a national system administered by the EPA that collects data on the generation and management of hazardous waste. BRS captures detailed data from two groups: Large Quantity Generators (LQG) and Treatment, Storage, and Disposal Facilities.

Date of Government Version: 12/31/95
Database Release Frequency: Biennially
Date of Last EDR Contact: 03/25/99
Date of Next Scheduled EDR Contact: 06/21/99

CONSENT: Superfund (CERCLA) Consent Decrees
Source: EPA Regional Offices
Telephone: Varies
Major legal settlements that establish responsibility and standards for cleanup at NPL (Superfund) sites. Released periodically by United States District Courts after settlement by parties to litigation matters.

Date of Government Version: Varies
Database Release Frequency: Varies
Date of Last EDR Contact: Varies
Date of Next Scheduled EDR Contact: N/A

FINDS: Facility Index System/Facility Identification Initiative Program Summary Report
Source: EPA
Telephone: N/A
Facility Index System. FINDS contains both facility information and 'pointers' to other sources that contain more detail. EDR includes the following FINDS databases in this report: PCS (Permit Compliance System), AIRS (Aerometric Information Retrieval System), DOCKET (Enforcement Docket used to manage and track information on civil judicial enforcement cases for all environmental statutes), FURS (Federal Underground Injection Control), C-DOCKET (Criminal Docket System used to track criminal enforcement actions for all environmental statutes), FFIS (Federal Facilities Information System), STATE (State Environmental Laws and Statutes), and PADS (PCB Activity Data System).

Date of Government Version: 04/01/99
Database Release Frequency: Quarterly
Date of Last EDR Contact: 04/16/99
Date of Next Scheduled EDR Contact: 07/12/99

HMIRS: Hazardous Materials Information Reporting System
Source: U.S. Department of Transportation
Telephone: 202-366-4526
Hazardous Materials Incident Report System. HMIRS contains hazardous material spill incidents reported to DOT.

Date of Government Version: 12/31/97
Database Release Frequency: Annually
Date of Last EDR Contact: 03/24/99
Date of Next Scheduled EDR Contact: 04/26/99

MLTS: Material Licensing Tracking System
Source: Nuclear Regulatory Commission
Telephone: 301-415-7169
MLTS is maintained by the Nuclear Regulatory Commission and contains a list of approximately 8,100 sites which possess or use radioactive materials and which are subject to NRC licensing requirements. To maintain currency, EDR contacts the Agency on a quarterly basis.

Date of Government Version: 12/08/98
Database Release Frequency: Quarterly
Date of Last EDR Contact: 03/02/99
Date of Next Scheduled EDR Contact: 05/31/99

NPL LIENS: Federal Superfund Liens
Source: EPA
Telephone: 205-564-4267
Federal Superfund Liens. Under the authority granted the USEPA by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) of 1980, the USEPA has the authority to file liens against real property in order to recover remedial action expenditures or when the property owner receives notification of potential liability. USEPA compiles a listing of filed notices of Superfund Liens.

Date of Government Version: 10/15/91
Database Release Frequency: No Update Planned
Date of Last EDR Contact: 02/22/98
Date of Next Scheduled EDR Contact: 05/24/99

PADS: PCB Activity Database System
Source: EPA
Telephone: 202-260-3936
PCB Activity Database. PADS Identifies generators, transporters, commercial storers and/or brokers and disposers of PCB's who are required to notify the EPA of such activities.

Date of Government Version: 09/22/97
Database Release Frequency: No Update Planned

Date of Last EDR Contact: 03/05/99
Date of Next Scheduled EDR Contact: 05/17/99

RAATS: RCRA Administrative Action Tracking System
Source: EPA
Telephone: 202-564-4104
RCRA Administration Action Tracking System. RAATS contains records based on enforcement actions issued under RCRA pertaining to major violators and includes administrative and civil actions brought by the EPA. For administration actions after September 30, 1995, data entry in the RAATS database was discontinued. EPA will retain a copy of the database for historical records. It was necessary to terminate RAATS because a decrease in agency resources made it impossible to continue to update the information contained in the database.

Date of Government Version: 04/17/95
Database Release Frequency: No Update Planned

Date of Last EDR Contact: 03/15/99
Date of Next Scheduled EDR Contact: 06/14/99

ROD: Records Of Decision
Source: NTIS
Telephone: 703-416-0223
Record of Decision. ROD documents mandate a permanent remedy at an NPL (Superfund) site containing technical and health information to aid in the cleanup.

Date of Government Version: 01/31/99
Database Release Frequency: Annually

Date of Last EDR Contact: 04/19/99
Date of Next Scheduled EDR Contact: 07/19/99

TRIS: Toxic Chemical Release Inventory System
Source: EPA
Telephone: 202-260-1531
Toxic Release Inventory System. TRIS identifies facilities which release toxic chemicals to the air, water and land in reportable quantities under SARA Title III Section 313.

Date of Government Version: 12/31/97
Database Release Frequency: Annually

Date of Last EDR Contact: 04/01/99
Date of Next Scheduled EDR Contact: 06/28/99

TSCA: Toxic Substances Control Act
Source: EPA
Telephone: 202-260-1444
Toxic Substances Control Act. TSCA identifies manufacturers and importers of chemical substances included on the TSCA Chemical Substance Inventory list. It includes data on the production volume of these substances by plant site.

Date of Government Version: 12/31/94
Database Release Frequency: Every 4 Years

Date of Last EDR Contact: 04/26/99
Date of Next Scheduled EDR Contact: 07/26/99

Historical and Other Database(s)

Depending on the geographic area covered by this report, the data provided in these specialty databases may or may not be complete. For example, the existence of wetlands information data in a specific report does not mean that all wetlands in the area covered by the report are included. Moreover, the absence of any reported wetlands information does not necessarily mean that wetlands do not exist in the area covered by the report.

Former Manufactured Gas (Coal Gas) Sites: The existence and location of Coal Gas sites is provided exclusively to EDR by Real Property Scan, Inc. ©Copyright 1993 Real Property Scan, Inc. For a technical description of the types of hazards which may be found at such sites, contact your EDR customer service representative.

Disclaimer Provided by Real Property Scan, Inc.

The information contained in this report has predominantly been obtained from publicly available sources produced by entities other than Real Property Scan. While reasonable steps have been taken to insure the accuracy of this report, Real Property Scan does not guarantee the accuracy of this report. Any liability on the part of Real Property Scan is strictly limited to a refund of the amount paid. No claim is made for the actual existence of toxins at any site. This report does not constitute a legal opinion.

DELISTED NPL: NPL Deletions
Source: EPA
Telephone: N/A
The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) establishes the criteria that the EPA uses to delete sites from the NPL. In accordance with 40 CFR 300.425.(e), sites may be deleted from the NPL where no further response is appropriate.

Date of Government Version: 04/23/99

NFRAP: No Further Remedial Action Planned
Source: EPA
Telephone: 703-413-0223
As of February 1995, CERCLIS sites designated "No Further Remedial Action Planned" (NFRAP) have been removed from CERCLIS. NFRAP sites may be sites where, following an initial investigation, no contamination was found, contamination was removed quickly without the need for the site to be placed on the NPL, or the contamination was not serious enough to require Federal Superfund action or NPL consideration. EPA has removed approximately 25,000 NFRAP sites to lift the unintended barriers to the redevelopment of these properties and has archived them as historical records so EPA does not needlessly repeat the investigations in the future. This policy change is part of the EPA's Brownfields Redevelopment Program to help cities, states, private investors and affected citizens to promote economic redevelopment of unproductive urban sites.

Date of Government Version: 04/21/99
Date Made Active at EDR: 06/09/99

PWS: Public Water Systems
Source: EPA/Office of Drinking Water
Telephone: 202-260-2805
Public Water System data from the Federal Reporting Data System. A PWS is any water system which provides water to at least 25 people for at least 60 days annually. PWSs provide water from wells, rivers and other sources.

PWS ENF: Public Water Systems Violation and Enforcement Data
Source: EPA/Office of Drinking Water
Telephone: 202-260-2805
Violation and Enforcement data for Public Water Systems from the Safe Drinking Water Information System (SWDIS) after August 1995. Prior to August 1995, the data came from the Federal Reporting Data System (FRDS).

Area Radon Information: The National Radon Database has been developed by the U.S. Environmental Protection Agency (USEPA) and is a compilation of the EPA/State Residential Radon Survey and the National Residential Radon Survey. The study covers the years 1986 - 1992. Where necessary data has been supplemented by information collected at private sources such as universities and research institutions.

EPA Radon Zones: Sections 307 & 309 of IRAA directed EPA to list and identify areas of U.S. with the potential for elevated indoor radon levels.

Oil/Gas Pipelines/Electrical Transmission Lines: This data was obtained by EDR from the USGS in 1994. It is referred to by USGS as GeoData Digital Line Graphs from 1:100,000-Scale Maps. It was extracted from the transportation category including some oil, but primarily gas pipelines and electrical transmission lines.

Sensitive Receptors: There are individuals deemed sensitive receptors due to their fragile immune systems and special sensitivity to environmental discharges. These sensitive receptors typically include the elderly, the sick, and children. While the location of all sensitive receptors cannot be determined, EDR indicates those buildings and facilities - schools, daycares, hospitals, medical centers, and nursing homes - where individuals who are sensitive receptors are likely to be located.

USGS Water Wells: In November 1971 the United States Geological Survey (USGS) implemented a national water resource information tracking system. This database contains descriptive information on sites where the USGS collects or has collected data on surface water and/or groundwater. The groundwater data includes information on more than 900,000 wells, springs, and other sources of groundwater.

Flood Zone Data: This data, available in select counties across the country, was obtained by EDR in 1999 from the Federal Emergency Management Agency (FEMA). Data depicts 100-year and 500-year flood zones as defined by FEMA.

NWI: National Wetlands Inventory. This data, available in select counties across the country, was obtained by EDR in March 1997 from the U.S. Fish and Wildlife Service.

Epicenters: World earthquake epicenters, Richter 5 or greater
Source: Department of Commerce, National Oceanic and Atmospheric Administration

Water Dams: National Inventory of Dams
Source: Federal Emergency Management Agency
Telephone: 202-646-2801
National computer database of more than 74,000 dams maintained by the Federal Emergency Management Agency.

New York Public Water Wells
Source: New York Department of Health

1 Introduction

On behalf of Consolidated Edison Company of New York, Inc. (Con Edison), Henningson, Durham and Richardson Architecture and Engineering, P.C. (HDR) has performed a Supplemental Site Investigation to provide an update of the subsurface conditions of Parcel II (the Site) at the former North First Street Terminal (NFST) Major Oil Storage Facility (MOSF) in Williamsburg, Brooklyn, NY (Figure 1). The investigation was performed in accordance with the Supplemental Remedial Investigation Work Plan prepared by Con Edison, dated November 17, 2016. A few scope items were modified based on observations during a preparatory site visit, which were documented in an email to the New York State Department of Environmental Conservation (NYSDEC) dated January 20, 2017, and approved on February 1, 2017 (Appendix A).

Parcel II is the location of the former #6 fuel oil storage Complex A, also known as the South Complex, of the NFST MOSF (Figure 2). The MOSF was decommissioned in 2012. NYSDEC issued a letter dated July 24, 2012 indicating no further action was required in relation to the former MOSF (MOSF No. 2-1480). However, the letter did note elevated concentrations of the volatile organic compounds (VOCs) toluene, xylene, and acetone at Complex A, apparently related to the Fyn Paint & Lacquer Company (Fyn Paint) facility located on an adjacent upgradient property. Conditions at this portion of Parcel II are the subject of this investigation. The Fyn Paint property, located at 230 Kent Avenue, is hydrogeologically and topographically up-gradient of the Site. Figure 2 shows the location of the Parcel II in relation to the Fyn Paint property.

1.1 Objective

The objective of this investigation was to further delineate the extent of the volatile organic compound (VOC) contamination at the Site, apparently emanating from the Fyn Paint property. This investigation also provides an update of previous environmental investigations associated with the NFST MOSF closure, which showed the Site has been impacted by the former Fyn Paint factory, specifically at the southeast corner area of the Site, directly downgradient from the former paint factory.

This Supplemental Site Investigation is a follow up to the 2015 Site Investigation of Parcel II, which was based, in part, on the March 2013 Supplemental Remedial Investigation Work Plan (SRIWP) prepared by Leggette, Brashears & Graham, Inc. (LBG) and submitted on behalf of Fyn Paint to the New York State Department of Environmental Conservation (NYSDEC) as part of the Fyn Paint Voluntary Cleanup Agreement (VCA) associated with the Fyn Paint site. Under the VCA, NYSDEC designated Parcel II as a separate Operable Unit (OU), identified as OU-2. To our knowledge, a new or prospective new owner (Kent Riverview LLC) entered the NYSDEC Brownfield Cleanup Program (BCP) as described in a NYSDEC Fact Sheet dated April 2016.

For evaluation purposes, this Supplemental Site Investigation Report (SSIR) compares analytical results with the DEC Part 375 Restricted Use Residential and Protection of Groundwater Soil Cleanup Objectives (SCOs) as well as the Restricted Use Industrial SCOs for the current zoning/site use. Groundwater data is compared to NYSDEC

Division of Water Technical & Operational Guidance Series 1.1.1 Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations dated June 1998; amended 1999, 2000, and 2004.

1.2 Site Overview

Parcel II is in a predominately mixed residential and commercial community. Historically, the Site vicinity was predominantly manufacturing, but in recent years manufacturing areas have been rezoned. Residences are now located to the north of Parcel I (Complex B, situated north of Metropolitan Avenue), across North Third Street. Commercial and light manufacturing properties northeast of the Site (across River Street from Parcel I) have recently been displaced. To the east of Parcel II is a closed paint factory (Fyn Paint) undergoing remediation under the BCP (Site No. C224154). A New York Power Authority (NYPA) Gas Turbine Generation Station is located to the south of Parcel II, across North First Street. The East River is to the west of Parcel II.

Based on the engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; Parcel II (Former Complex A) consisted of three steel tanks with the following capacities:

- T-100 – 6,000,000 gallons
- T-200 – 2,325,000 gallons
- T-300 – 6,000,000 gallons

These tanks were out of service and subsequently demolished in 2012. The MOSF was officially closed by NYSDEC as documented in a letter dated July 24, 2012.

1.3 Previous Investigations

In 2011, HDR conducted a Site Investigation of the MOSF perimeter by advancing borings along the east, north and south sides of both Complex A (Parcel II) and B (Parcel I). For this investigation, 18 soil borings were advanced to assess subsurface conditions. Soil samples were collected and analyzed for VOCs, semi-volatile organic compounds (SVOCs), and metals. A subset of these samples was analyzed for polychlorinated biphenyls (PCBs) and pesticides. Results were compared to the NYSDEC Part 375 SCOs. No groundwater samples were collected during this investigation.

Analytical results show that the SVOCs appeared to be related to urban fill and did not appear to be associated with No. 6 fuel oil. No apparent indication of impacts to soil caused by leakage from any of the tanks, ancillary piping, accidental discharges or other Site activities was observed. However, impacted subsurface soil was encountered at the perimeter of the Complex A (Parcel II) tank farm, in proximity to the upgradient Fyn Paint property. Migration of impacted groundwater is further supported by the historical groundwater sample results of monitoring wells installed along the east and south sides of Complex A, where toluene, ethylbenzene, xylenes and other paint manufacturing related chemicals have been detected at concentrations up to four orders of magnitude above the standards/guidance values. This investigation and the associated analytical results are documented in the Site Investigation Report (HDR 2011).

In 2012, HDR conducted a “Footprint” investigation to assess the environmental conditions directly under the concrete footprint of the MOSF Complexes A and B. As part of this “Footprint” investigation, a surface soil assessment as well as deeper subsurface soil assessment was completed, after demolition of the tank complexes. Based on DEC DER-10 guidance, 42 soil borings were advanced during the 2012 “Footprint” Site Investigation. HDR also installed nine temporary piezometers within the footprint of the former tank complexes to assess the groundwater conditions beneath the former tank farm. Five piezometers were installed in Complex A and four piezometers were installed in Complex B. These piezometers were removed following this investigation.

Results of the Footprint Investigation concluded that the Site soil consists of urban fill. Analytical data for VOCs, SVOCs, pesticides, PCBs and metals were generally consistent with the chemical composition of urban fill or associated with creosote treated wood piles, which exist at Complex B only (concrete piles supported the Complex A tank farm). At the Site (Complex A), there appears to be two primary areas where elevated chemical constituent concentrations were detected. One area is at the southeast corner of the complex, near the intersection of North First Street and River Street and the other area is near the East River, at the northwest corner of Complex A.

In the southeast area of the Site, VOCs apparently have migrated from the Fyn Paint facility and impacted this area. Concentrations of ethylbenzene, toluene and total xylenes were detected in the double to triple digit milligram per kilogram (mg/kg) or part per million (ppm) range in the 2012 subsurface soil sample (FP A-3) collected at the water table in this area. Based on the results of the 2012 soil samples collected from the surrounding borings (FP A-2, FP A-4, and FP A-5), the impacted area did not appear to extend far onto the Site.

The second impacted area of the Site is near the East River, at the northwest corner of Complex A. This area appeared to be impacted by polycyclic aromatic hydrocarbons (PAHs) as evidenced by certain SVOCs exceeding the Unrestricted Use SCOs in subsurface soil samples. A separate fill source from the remainder of Complex A was the suspected source as no other sample locations within Complex A had PAH concentrations on this order of magnitude. The investigation and results are documented in the Site Investigation Report, Second Phase, In support of Voluntary MOSF License Termination, HDR, June 2012.

At the request of NYSDEC, HDR, on behalf of Con Edison, conducted an investigation in 2015 to assess Site conditions in Parcel II (Complex A) associated with VOC impacts from an off-Site source. As part of this investigation, nine soil borings were advanced near the southeast corner of Parcel II. Soil samples were collected from these boring locations. One sample, PZ A-06 (6’) was reported to have concentrations above the Part 375 Restricted Residential Use and Protection of Groundwater SCOs. Concentrations of three compounds, ethylbenzene (22 mg/kg), total xylene (135 mg/kg), and toluene (2.3 mg/kg) exceeded the Protection of Groundwater Use SCOs of 1 mg/kg, 1.6 mg/kg, and 0.7 mg/kg, respectively for this sample. Total xylene (135 mg/kg) was the only VOC detected at a concentration that exceeded the Restricted Residential Use SCOs. After the borings reached the termination depths, piezometers were installed for subsequent groundwater sample collection. Analytical results show that 10 VOCs were detected in Site groundwater above applicable TOGS 1.1.1 GWQS or guidance values. These VOCs

include cis-1,2-dichloroethene, vinyl chloride, 1,1-dichloroethane, isopropylbenzene, trichloroethene, methyl tert butyl ether (MTBE), benzene, ethylbenzene, total xylenes and toluene were the VOCs detected above the GWQS or guidance values at Parcel II. Toluene, ethylbenzene, and total xylenes were detected in concentrations that are four orders of magnitude above the GWQS and guidance values. These VOCs are typically not indicative of No. 6 fuel oil, especially at these concentrations.

2 Parcel II Investigation

This Investigation was completed to supplement/update the Site Investigation for Parcel II in 2015 and was conducted in accordance with the DEC-approved Supplemental Remedial Investigation Work Plan, including the modifications noted in an email correspondence dated January 20, 2017, and approved by the NYSDEC on February 1, 2017 (Appendix A). Borehole and monitoring well locations are shown on Figure 3.

In addition to the approved work plan, the investigation was also completed in accordance with the Site specific Health and Safety Plan (HASP), which was approved by Con Edison prior to the start of the field activities.

On January 12, 2017, a kick off meeting was held with representatives from Con Edison and HDR participating. During this meeting, borehole locations for this investigation were tentatively identified based on the prior piezometer locations and Site topography. At the time of the Site visit, these locations were considered tentative pending NYSDEC approval and subsequent results of a geophysical survey and subsurface utility clearance ("soft dig") activities associated with the intrusive activity.

The field activities consisted of three primary tasks:

- utility mark-out, survey and hand clearing;
- soil borings with sampling and monitoring well installation; and
- groundwater sampling.

Each task is discussed below.

2.1 Utility Mark-Out and Soft Dig

Prior to the mobilization of drilling equipment, HDR contracted utility mark-out services through Aquifer Drilling & Testing, Inc. (ADT) of Mineola, New York, to mark out utilities and other potential underground anomalies within the work area. Nova Geophysical Engineering (Nova) of Douglaston, NY mobilized to the Site to implement the geophysical investigation. On January 23, 2017, Nova employed ground penetrating radar (GPR) technology using a Noggin 250 MHz GPR shielded antenna and a 3M Dynatel® 2250M-iD Cable/Pipe Locator to locate subsurface obstructions/anomalies. A series of parallel traverses, in both the north/south and east/west directions were established and detected targets were marked in the field using paint and or pin flags. Due to what is believed to be the presence of historic MOSF tank support piles in the areas where certain borehole locations were proposed, three locations were offset approximately 18 inches to stay clear of the potential subsurface obstructions.

Other than concrete piles to support the former Tank Complex A (several of which were visible at ground surface), no subsurface anomalies were identified during the geophysical survey. Nova provided figures from their survey, which are included in Appendix B.

As an added precaution and part of the Con Edison intrusive investigation program, the upper 5 feet of each soil boring was excavated using non-mechanical methods to confirm the absence of utilities (soft dig). ADT was contracted to provide soft dig services in advance of the drilling operations. Before intrusive work commenced, ADT initiated the

One Call notification system as required by New York State Code Rule 753-3.2. ADT's hand clearing crew mobilized to the Site on February 1, 2017 to clear three borehole locations using vacuum and hand dig techniques prior to intrusive activities. Each location was cleared to a depth of five feet below ground surface (bgs); after the location was cleared, the soils were placed back in the hole and the location was marked for subsequent drilling and well installation. A description of the materials encountered during the soft dig is provided in the geologic logs (Appendix C). No obvious sign of impact by odor, staining or field instrument reading was noted during the soft dig activities.

2.2 Soil Borings

On February 2 and 3, 2017, ADT mobilized a CME 55 drill rig to the Site for the advancement of the soil borings (Figure 3) to characterize subsurface soil conditions and allow for the collection of soil samples for laboratory analysis.

An HDR environmental scientist was on-Site during the drilling activities to log soils and collect soil samples for laboratory analyses. Upon collection, samples were immediately screened with the PID to assess whether organic vapors were present. If organic vapors were noted, a sample of that interval representing a worst case situation could be collected for laboratory analyses. Soils from each boring were then described in accordance with the Unified Soil Classification System (USCS) for material type and composition, color, grain size and distribution, depth to water, visual or olfactory evidence of contamination, as well as any other distinctive characteristics. This information was documented on geologic logs which are included as Appendix C.

All borings were advanced continuously in five-foot increments using a 2-inch diameter Macrocore® barrel with dedicated PVC liners. The SB/SMW-A borehole was advanced to 15 feet bgs, and the SB/SMW-C borehole was advanced to 18 feet bgs. SB/SMW-C was advanced to a greater depth to vertically delineate the PID readings measured at this location.

During intrusive activities, HDR screened the headspace above the location to monitor for organic vapors using a Rae Systems MultiRae 3000 photoionization detector (PID) with a 10.6 eV lamp. Elevated PID readings were not detected during the intrusive activities at SB/SMW-A. However, PID monitoring at SB/SMW-C detected readings up to 1407 ppm units, starting at the water table (about 5 feet bgs) and decreasing with depth. Moderate to slight odors were also noted at SB/SMW-C. This location is near the southeast corner of the Site, where VOC impacts were previously identified. The water table in this area is about 5-6 feet below grade.

Soils were classified during the intrusive activities and recorded on geologic logs (Appendix C). Typically, soils above the water table consisted of silty sands with varying amounts of brick, concrete, gravel and cobbles. Soils below the water table were described generally as fine to medium sand and/or silt. Upon reaching the termination depth of each borehole, a monitoring well consisting of a 2-inch diameter, 10 foot long screen was installed.

Based on the field observations, the contingent boring, SB-B, was not advanced. SB-B was to be installed if evidence of contamination was noted in SB-A. No evidence of contamination was observed during the utility clearance of SB-A. The location where SB-

C was installed is closer to the existing piezometer PZA-06 than originally intended; however, the location is between PZA-06 and PZA-09, meeting the intent of the approved work plan.

Soil cuttings generated during the subsurface investigation were containerized in three (3) DOT rated 55-gallon drums and staged on-Site for waste characterization sampling and subsequent off-Site disposal. On February 15, 2017, soil cuttings were sampled for waste characterization parameters. Results of the waste characterization were forwarded to Con Edison on March 2, 2017 and the waste was removed by Con Edison on March 13, 2017 for subsequent disposal at Triumvirate Environmental in Astoria New York.

2.2.1 Soil Sampling and Analysis

As part of this Site investigation, four (4) subsurface soil samples were collected for lab analysis. One sample from each boring was retained from either the depth which exhibited the highest PID reading or the interval directly above the water table. A second sample was collected to vertically delineate the extent of impacted soil. Soils for analysis were transferred from dedicated PVC liners directly into laboratory provided glassware. Each container was then labeled with the appropriate sample identification number and sample depth, the analytical parameters to be analyzed, the date and time of sampling, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to Hampton-Clarke, Inc., in Fairfield, NJ, a NYSDOH certified laboratory, via laboratory-provided courier. Soil samples submitted to the laboratory were analyzed for VOCs using EPA Method 8260C and SVOCs using EPA Method 8270D. Additionally, quality assurance/quality control (QA/QC) samples, including a trip blank (VOCs), and one field blank and one duplicate sample (VOCs and SVOCs) were collected and submitted for laboratory analysis.

Upon completion of each borehole, all sampling equipment (e.g., Macrocore® sampler) was decontaminated with an Alconox and tap water wash, followed by a de-ionized or distilled water rinse. Drill cuttings were placed in a DOT-rated drum for subsequent waste characterization sampling and off Site disposal.

2.3 Monitoring Well Installation

Upon reaching the termination depth for each borehole, a 10 foot length of 2 inch diameter schedule 40 polyvinyl chloride (PVC), 0.010 inch slot screen (10 slot) coupled to a PVC riser section was placed in the borehole such that the screened section of each piezometer intersected the groundwater table and the finished height of each well was about 0.5 feet below ground surface. The annular space around the well was backfilled with well-grade type sand to a minimum of one foot above the well screen. The annular space above the sand pack was completed with a bentonite seal. Each monitoring well was finished off with a compression fit plug and flush mount protective casing. Monitoring well construction logs documenting the construction details are included as Appendix D. Locations of the monitoring wells are shown on Figure 3.

Following installation, the two new monitoring wells were developed on February 3, 2017, using a peristaltic pump with dedicated tubing. During development, the monitoring wells were periodically surged using the pump in an attempt to remove fine grained sediments that may have been entrained within the borehole. During purging, the

discharge water was periodically screened using a turbidity meter. Well development for each well continued until the water was less than 50 nephelometric turbidity units (NTUs) or for duration of one hour, whichever occurred first. For SMW-A, development was terminated after 1 hour as the final turbidity reading was 160 NTUs, and not decreasing. For SMW-C, the final turbidity was 32 NTUs after one hour of development. Approximately 50 gallons of purge water was generated per well during the development. Development water was containerized and staged in DOT-rated 55 gallon drums on-Site for waste characterization on February 15, 2017 and off-Site disposal on March 13, 2017.

2.3.1 Groundwater Sampling and Analysis

Upon completion of groundwater gauging, one groundwater sample was collected from the two new monitoring wells, four existing monitoring wells and two existing piezometers. Sampling occurred on February 14 and 15, 2017. Dedicated ¼-inch, inside diameter (ID) low density polyethylene (LDPE) tubing was placed into each monitoring well and piezometer and connected to a variable speed peristaltic pump utilizing laboratory-grade silicone tubing. HDR sampled the six monitoring wells and two piezometers following low flow sampling methods with one modification, turbidity was considered stable at three consecutive readings within 10 percent deviation or three consecutive readings below 10 NTUs. The other field chemistry parameters (temperature, conductivity, pH, dissolved oxygen, total dissolved solids and oxidation reduction potential) stabilized during the purging activities. Groundwater sampling logs are included as Appendix E.

Once stable groundwater water quality conditions were reached, groundwater samples were collected and placed directly into laboratory supplied glassware. Each container was then labeled with the appropriate sample identification number, parameters to be analyzed, date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to Hampton-Clarke, Inc., in Fairfield, NJ, a NYSDOH certified laboratory, via laboratory-provided courier.

Purged water was collected in a five (5) gallon pail and subsequently transferred into DOT-rated 55 gallon drums with the well development water. Following groundwater sampling, a waste classification sample of the development and purge water was collected and submitted to Hampton-Clarke for analyses. Waste characterization samples were collected on February 15, 2017 followed by off-Site disposal on March 13, 2017.

All groundwater samples were analyzed for VOCs using EPA Method 8260C and SVOCs using EPA Method 8270B. QA/QC sampling, including a field blank sample and a duplicate sample, were also collected (for VOCs and SVOCS) and sent to Hampton-Clarke for analysis. A trip blank sample was also collected and sent to Hampton-Clarke for VOC analysis only.

During the groundwater sampling activities, each location was surveyed for location and elevation using survey grade Differential Global Positioning System (DGPS). Elevation measurements were based on the NAVD88 survey datum and the horizontal data are based on the New York State Plane Long Island NAD83 coordinate system.

3 Investigation Results

3.1 Soil Sampling

Analytical results of the samples collected during this Investigation were compared to NYSDEC Part 375 Soil Cleanup Objectives (SCOs) for Restricted Residential Use and Protection of Groundwater as well as the Restricted Use Industrial SCOs for the current zoning/site use. Based on the laboratory analytical results of the four samples, the soils across the Site generally appear consistent with prior sampling results.

A summary of the analytical results with comparison to use based SCOs is included as Table 1A and on Figure 4A. A comparison of the results to Protection of Groundwater SCOs is included as Table 1B and Figure 4B. The laboratory analytical data package is provided as Appendix F.

Samples collected from SB-C were reported to have concentrations above the Part 375 Restricted Residential Use and Protection of Groundwater SCOs. Concentrations of three compounds, ethylbenzene, total xylene, and toluene exceeded the Protection of Groundwater Use SCOs of 1 mg/kg, 1.6 mg/kg, and 0.7 mg/kg, respectively for the two samples collected from SB-C. Total xylene and ethylbenzene were also detected at concentrations that exceeded the Restricted Residential Use SCOs. Ethylbenzene (170 mg/kg), toluene (22 mg/kg) and total xylenes (750 mg/kg were detected in the sample collected from 5 to 6 feet bgs. In the sample collected from 10 to 11 feet bgs at SB-C, ethylbenzene (34 mg/kg), toluene (3.6 mg/kg) and total xylenes were detected. For the samples collected at SB-A, only the total xylenes concentrations exceeded the Protection of Groundwater Use SCO. Concentrations of total xylenes were 1.8 mg/kg for the sample collected at 5 to 6 feet bgs and 2.6 mg/kg for the sample collected at 10 to 11 feet bgs. The ethylbenzene, total xylenes, and toluene concentrations detected at this location are likely attributable to contamination migrating from the Fyn Paint facility located upgradient directly to the east.

No other VOCs were detected at concentrations exceeding the Restricted Residential or Protection of Groundwater SCOs in the four samples collected from the two borings.

Results of the SVOC analyses showed no exceedances of the Restricted Residential SCOs or the Protection of Groundwater SCOs. Although certain SVOCs were detected, those compounds were reported at concentrations below the Unrestricted Use SCOs.

3.2 Groundwater Sampling

To assess groundwater quality and further delineate the impacted groundwater at Parcel II, groundwater samples were collected from the two new monitoring wells. In addition, groundwater samples were collected from four existing monitoring wells (MW-4, MW-10, MW-12, and MW-14) and two existing piezometers (PZA-06 and PZA-09) in this area. A summary of the analytical data is included as Table 2. Analytical data packages are provided as Appendix G. Figure 5 shows the analytical data associated with the sample locations.

Analytical results show that 6 VOCs were detected in Site groundwater above applicable TOGS 1.1.1 GWQS or guidance values. These VOCs include cis 1,2-dichloroethene, 1,1-dichloroethane, isopropylbenzene, ethylbenzene, total xylenes and toluene. Toluene, ethylbenzene, and total xylenes were detected in concentrations that are up to four orders of magnitude above the GWQS and guidance values in four (4) samples: SMW-A, SMW-C, PZA-06, and MW-12. Isopropylbenzene was detected in one sample, SMW-C at 220 ug/l, which is two orders of magnitude above the groundwater standard of 5 ug/l. These VOCs are typically not indicative of No. 6 fuel oil at these concentrations. The origin of these compounds is likely associated with the Fyn Paint and Lacquer site, which is upgradient of Parcel II. During the Fyn Paint investigations, elevated concentrations of ethylbenzene, total xylenes and toluene were detected in a source area with downgradient sample results showing lesser concentrations between the Fyn Paint and Con Edison properties, indicating migration to the west towards Parcel II.

Chlorinated VOCs including 1,1-dichloroethane, cis-1,2-dichloroethene, and trichloroethene were detected in three samples: MW-4, MW-14, and PZA-06. In PZA-06, the cis-1,2-dicholorethene was detected at 9.1 ug/l, above the groundwater standard of 5 ug/l. At MW-4, the 1,1-dichloroethance concentration was reported at 2 ug/l, above the groundwater standard of 0.6 ug/l. Trichloroethene was detected in one sample (MW-14); however, the concentration was below the groundwater standard of 5 ug/l. The source of cis-1,2-dichloroethene, 1,1-dichloroethane and trichloroethene is not known. These compounds are not associated with No. 6 fuel oil.

Acetone concentrations were below detection limits in each of the wells sampled. However, the detection limits of the MW-12, SMW-A and SMW-C samples were elevated due a dilution factor associated with the concentrations reported for these samples.

The only other VOC that was detected during groundwater sampling was MTBE. MTBE was detected in two samples, MW-4 at 0.92 ug/l and PZA-09 at 1.4 ug/l, both below the groundwater standard of 10 ug/l. The origin of the MTBE is unknown. MTBE is associated with gasoline and not associated with No. 6 fuel oil.

Results of the SVOC groundwater analyses shows four phenols were detected at concentrations that exceed the groundwater standard for total phenols (1 ug/l). These phenols include phenol, 2,4-dimethylphenol, 2-methylphenol, and 3&4-methylphenol. One or more of these phenols were detected in PZA-06 (total phenols are 17.7 ug/l), SMW-A (67.1 ug/l), SMW-C (117 ug/l), and MW-12 (164 ug/l). No other SVOCs were detected in concentrations exceeding the respective groundwater criteria. Limited historic data regarding phenols is available as the prior sampling for SVOC consisted of the base neutral compound analyses only. The source of phenols is not known. However, phenols are used to make resins. Resins serve as binders for paint.

3.3 Groundwater Elevations

Depth to groundwater measurements collected prior to groundwater sampling were used to establish the groundwater elevations and groundwater contours for the Site. In addition, all wells were surveyed using the DGPS to ensure all measuring points were from a consistent datum (NAVD88). Based on these measurements, the groundwater elevations range from 3.36 feet at MW-12 to 2.12 feet at SMW-A and MW-10. Generally, groundwater flows from east to west, toward the East River based on groundwater

elevation data collected during the Fyn Paint VCA activities. A summary of the groundwater elevations as measured prior to groundwater sampling is provided in the table below. Groundwater elevations are shown on Figure 6.

Well	Measuring Point Elevation	Depth to Water from Measuring Point	Groundwater Elevation
MW-4	14.84	12.44	2.4
MW-10	13.47	11.35	2.12
MW-12	14.28	10.92	3.36
MW-14	15.42	13.2	2.22
SMW-A	6.57	4.45	2.12
SMW-C	5.89	3.54	2.35
PZA-06	8.5	6.24	2.26
PZA-09	7.28	4.59	2.69

At PZA-09, the higher groundwater elevation may be the result of recent precipitation considering Parcel II is no longer covered with the MOSF. This area may be acting in part as a recharge basin from adjacent asphalt and concrete covered areas. Recent precipitation and infiltration of standing water may further affect the groundwater elevations locally due to the piezometer construction, such as at PZA-09, which was installed in a smaller diameter (i.e., Geoprobe) hole without a bentonite seal as opposed to the monitoring wells which were installed with an appropriate sand pack and bentonite seal. At MW-12, the groundwater level has historically been higher than nearby wells. MW-12 was installed near an old fire hydrant. Any leakage from the hydrant may affect groundwater levels with the effect of the potential leakage decreasing with distance from the hydrant. Due to these variations and the small area of investigation, the groundwater elevations were not contoured.

4 Discussion

Based on a comparison of the groundwater data with the prior investigations in the vicinity of Complex A, the subsurface conditions appear to be relatively unchanged. Contaminants of concern and concentrations detected in 2017 are generally consistent with the 2015 and 2012 data. However, toluene, ethylbenzene and xylenes concentrations detected near the southeast corner of Parcel II (PZ A-06) were lower than the concentrations detected in 2015 and 2012 (Sample FP A-1), by an order of magnitude.

Concentrations detected in the newly installed SMW-C, installed north of PZA-06, are similar to the prior concentrations detected in PZA-06 in 2015 and in temporary point PZ-A-1 in 2012. PZA-06 was installed in 2015 in attempt to confirm the results of PZ-A-1. PZ-A-1 was removed following the 2012 sampling as it was a temporary sampling point installed for the MOSF closure.

In 2012, a temporary point (PZ-A-4) was installed north of SMW-C. Groundwater sampling results from that location showed concentrations of total xylenes (24,000 ug/l), ethylbenzene (4,700 ug/l), and styrene (6.3 ug/l) were above the groundwater criteria but lower than the concentrations detected in PZ-A-1 (HDR 2012). Delineation of PZ-A-1 occurred in 2015 with the installation and sampling of PZ-A-10 (to the southwest), PZ-A-11 (west), PZ-A-12 (northwest) and PZ-A-13 (north), where the toluene, ethylbenzene and total xylenes concentrations were below the groundwater criteria (HDR 2015).

In comparison with the quarterly sampling results discussed in the 2011 report (first quarter 2009 through first quarter 2011), the contaminant concentrations in MW-4 and MW-10 have decreased, generally from single or double digit part per billion concentrations to non-detect.

Results of the groundwater sample collected from MW-12 are generally consistent with the historic results. However, the total xylenes concentration (74,000 ug/l) exceeds the highest concentration over those nine quarters. The contamination at MW-12 was previously delineated in 2015 with the installation and sampling of PZA-11, PZA-12, and PZA-13 (Figure 3).

Results of groundwater sampling at MW-14, near the southeast corner of Parcel II, remain below the groundwater criteria. The geologic log for MW-14 does not indicate any contaminant impact, visually, by odor, or by instrument reading. In 2003, a soil sample collected from the water table in the MW-14 boring confirms the lack of contamination at this location.

Acetone was detected in the central portion of Parcel II during the 2012 investigation but was below detection limits for groundwater samples in 2015 and in 2017. Acetone was also associated with the Fyn Paint operations.

In summary, consistent with the 2015 and 2012 investigations, the data obtained during this investigation confirm historic operations at the Fyn Paint facility have impacted the southeastern corner of the Parcel II property with dissolved phased VOCs. However, the horizontal extent of the impact appears to be limited to the southeast corner of Parcel II.

Notes:
1. All results are in mg/kg
2. Highlighted cells indicate exceedances of NYSDEC Part 375 Table375-6.8(b) Soil Cleanup Objectives (SCO).
3. U = not detected at the reporting limit.
4. Bold values indicate detected results.
5. NC = no regulatory criteria

Ms. Mobyed,

The NYSDEC has reviewed attached e-mail containing three proposed modifications to the SRIWP and found these modifications acceptable.

Thank you

Subject: North 1st Street Terminal - Parcel II Supplemental Remedial Investigation Summary & Schedule - REV 1/20/17

ATTENTION: This email came from an external source. Do not open attachments or click on links from unknown senders or unexpected emails.

Ms. Munteanu-Ramnic,

As a follow up to our conversation on Wednesday morning (1/18/17), please be advised that Con Edison completed a site walk on 1/12/17 in preparation for the upcoming investigation work planned at the NFST site located in Williamsburg, Brooklyn, New York. During the field walk an embankment (with a significant incline) was observed around the site perimeter where soil borings SB-D and SB-A/SMW-A are proposed in the approved Supplemental Remedial Investigation Work Plan North First Street MOSF – Parcel II Brooklyn, NY, dated November 11, 2016. The embankment is high and narrow, and appears to be filled with large rock material (~4"-8" diameter was observed), likely placed for erosion mitigation, which may obstruct the planned installation activities. Additionally, standing water and debris was observed across the low lying areas of the site in the locations where the remaining soil boring and monitoring well (SB-B and SB-C/SWM-C) locations are proposed, respectively.

All points are intended to be positioned with a minimum spacing of ~25ft between them. As indicated in the attached revised figure, the following proposed modifications to the approved locations are recommended:

- Sample existing well MW-10 in lieu of advancing the proposed boring SB-D, which is inaccessible due to the existing embankment
- Relocate soil boring SB-A/SMW-A to the north approximately 5 ft., at the foot of the existing incline; the point is currently located on the slope of the incline – making it infeasible for the rig to reach the location safely

- A contingent point (SB-B) is proposed approximately 25 ft. the west of SB-A; if impacts are identified during collection of boring SB-A, a step out boring and/or installation of a well downgradient, to the west between PZA-06 and PZA-09 will be considered
- No change to SB-C/SMW-C is proposed at this time

In accordance with the approved Supplemental Remedial Investigation Work Plan North First Street MOSF – Parcel II Brooklyn, NY, dated November 11, 2016, groundwater samples will also be collected from the two new wells SMW-A and SWM-B, existing wells PZ-06A and PZ-09A and updgradient wells MW- 4, MW-12 an MW-14 on the adjoining sidewalk of River Street to the east (upgradient) of wells PZ-06A and PZ-09A.

A revised schedule is provided below for your reference:

Task Name	Start	Finish	Duration (days)
FIELD PLANNING AND IMPLEMENTATION			
Schedule Fieldwork/Mobilization	1/19/17	1/27/2017	14
Site Walk/Inspection	1/27/2016	1/12/2017	complete
Develop HASP Addendum and Approval	1/9/17	1/20/2017	10
Geophysical Survey/Utility Mark-Out*	1/23/2017	1/24/2017	2
Vacuum Excavation Soil Boring/Gas Locations (to 5' bgs)	2/1/2017	2/3/2017	3
Soil Boring/MW Installation/Development	2/6/2017	2/10/2017	5
Groundwater Gauging/Sampling	2/21/2017	2/22/2017	2
REPORT PREPARATION			
Laboratory Analysis	2/23/2017	3/15/17	15
Draft Supplemental RI Report Preparation	3/6/17	3/31/17	20
Draft Supplemental RI Report review	4/3/17	4/14/17	10
NYDEC Review of Supplementary RI Report	4/17/17	5/12/17	20
Response to NYDEC Comments	5/12/17	5/26/17	10
Final RI Report	5/26/17	6/9/17	10

**Accelerated to be completed concurrent with the LBG sampling event on Parcel III of Con Edison's NFST station*
Red = revised

Thank you,

Kristin Mobyed

Additional Notes

Comments, Notes, Special Requirements, HAZARDS

Indicate if low-level methods required to meet current groundwater standards (SPLP for soil):
- ☐ BN or BNA (8270D SIM)
- ☐ VOC (8260C SIM or 8011)
- ☐ SPLP (BN, BNA, Metals)

For NNJ LSRP projects, indicate which standards need to be met:
- ☐ NJDEP GWQS
- ☐ NJDEP SRS
- ☐ NJDEP SPLP
- ☐ Other (specify):

Check if applicable:
- ☐ Project-Specific Reporting Limits
- ☐ High Contaminant Concentrations
- ☐ NJ LSRP Project (also check boxes above/right)

Cooler Temperature: 2.8

11) Sampler (print name): MILLS Date: 2/2/17

Please note NUMBERED items. If not completed your analytical work may be delayed.
A fee of $5/sample will be assessed for storage should sample not be activated for any analysis.

I Edward Schwetz, PG _____certify that I am currently a Qualified Environmental Professional as defined in 6 NYCRR Part 375 and that this Report was prepared in accordance with all applicable statutes and regulations and in substantial conformance with the DER Technical Guidance for Site Investigation and Remediation (DER-10) and that all activities were performed in full accordance with the DER-approved work plan and any DER-approved modifications.

This page is intentionally left blank.

1 Introduction

On behalf of Consolidated Edison Company of New York, Inc. (Con Edison), Henningson, Durham and Richardson Architecture and Engineering, P.C. (HDR) has performed a Site Investigation to provide an update of the subsurface conditions of Parcel II (the Site) at the former North First Street Terminal (NFST) Major Oil Storage Facility (MOSF) in Williamsburg, Brooklyn, NY (Figure 1). The investigation was performed in accordance with the Site Investigation Work Plan prepared by HDR, dated June 5, 2015, and approved by Con Edison on June 10, 2015.

Parcel II is the location of the former #6 fuel oil storage Complex A, also known as the South Complex, of the NFST MOSF (Figure 2). The MOSF was decommissioned in 2012. New York State Department of Environmental Conservation (NYSDEC) issued a letter dated July 24, 2012 indicating no further action was required in relation to the former MOSF (MOSF No. 2-1480). However, the letter did note elevated concentrations of the Volatile Organic Compounds (VOCs) toluene, xylene, and acetone at Complex A, apparently related to the Fyn Paint & Lacquer Company (Fyn Paint) facility located on a nearby property. The Fyn Paint property, located at 230 Kent Avenue, is hydrogeologically and topographically up-gradient of the Site. Figure 2 shows the location of the Site in relation to the Fyn Paint property.

1.1 Objective

The objective of this investigation was to delineate, to the extent possible and within the scope, the vertical and horizontal extent of the volatile organic compound (VOC) contamination at the Site apparently emanating from the Fyn Paint property. This investigation also provides an update of previous environmental investigations associated with the NFST MOSF closure, which showed the Site has been impacted by the former Fyn Paint factory, specifically at the southeast corner of the Site, directly downgradient from the former paint factory.

This Site Investigation was based on NYSDEC approved elements of the March 2013 Supplemental Remedial Investigation Work Plan (SRIWP) prepared by Leggette, Brashears & Graham, Inc. (LBG) on behalf of Fyn Paint as part of the Fyn Paint Voluntary Cleanup Agreement (VCA) associated with the Fyn Paint site. Under the VCA, NYSDEC designated Parcel II as a separate Operable Unit (OU), identified as OU-2. The LBG SRIWP was prepared to delineate the extent of VOC contamination and to estimate the hydrogeologic properties, develop a conceptual model of groundwater flow and to determine the contaminant migration fate and transport at the Site. Activities proposed in LBG's SRIWP included temporary groundwater well installations, slug testing to estimate hydrogeologic properties, interceptor trench conceptual design, and permanent groundwater monitoring well installation to provide sampling points, monitor the contaminant migration and effectiveness of implemented remedial measures. LBG's SRIWP was never implemented, and HDR understands that NYSDEC terminated the Fyn Paint VCA in November 2014. HDR also understands that a prospective purchaser entered the Fyn Paint parcel into the NYSDEC Brownfield Cleanup Program (BCP) as a Volunteer on March 5, 2015.

Information gathered during this investigation will be used to assist in the future determinations of Site end use. For evaluation purposes, this Site Investigation Report (SIR) compares analytical results with the DEC Part 375 Restricted Residential Use and Protection of Groundwater Soil Cleanup Objectives (SCOs).

1.2 Site Overview

Parcel II is in a predominately mixed residential and commercial community. Historically, the Site vicinity was predominantly manufacturing, but in recent years manufacturing areas have been rezoned. Residences are now located to the north of Parcel I (Complex B, situated north of Metropolitan Avenue), across North Third Street. Commercial and light manufacturing properties northeast of the Site (across River Street from Parcel I) have recently been displaced. To the east of Parcel II is a closed paint factory known as the Fyn Paint parcel for which a prospective purchaser was admitted into the BCP as a Volunteer on March 5, 2015. A New York Power Authority (NYPA) Gas Turbine Generation Station is located to the south of Parcel II, across North First Street. The East River is to the west of Parcel II.

Based on the engineering drawings prepared by Leonard B. Goldman, P.E., Consulting Engineer, dated October 4, 1963; Parcel II (Former Complex A) consisted of three tanks with the following capacities:

- T-100 – 6,000,000 gallons
- T-200 – 2,325,000 gallons
- T-300 – 6,000,000 gallons

1.3 Previous Investigations

In 2011, HDR conducted a Site Investigation of the MOSF perimeter by advancing borings along the east, north and south sides of both Complex A and B. For this investigation, 18 soil borings were advanced to assess subsurface conditions. Soil samples were collected and analyzed for VOCs, Semi-Volatile Organic Compounds (SVOCs), and metals. A subset of these samples was analyzed for PCBs and pesticides. Results were compared to the NYSDEC Part 375 SCOs. No groundwater samples were collected during this investigation.

Analytical results show that the SVOCs appeared to be related to urban fill and did not appear to be associated with No. 6 fuel oil. No apparent indication of impacts to soil caused by leakage from any of the tanks, ancillary piping, accidental discharges or other Site activities was observed. However, impacted soil was encountered in subsurface soil at the perimeter of the Complex A tank farm, in proximity to the upgradient Fyn Paint property. Acetone was detected at concentrations exceeding the NYSDEC Part 375 Unrestricted Use SCOs in two samples. The presence of acetone in the soil suggests migration of impacted groundwater is occurring from the upgradient source at the Fyn Paint facility. Migration of impacted groundwater is further supported by the historical groundwater sample results of monitoring wells installed along the east and south sides of Complex A, where toluene, ethylbenzene, xylenes and other paint manufacturing related chemicals have been detected. This investigation and the associated analytical

results are documented in the Site Investigation Report (HDR 2011), which is included as Appendix A.

In 2012, HDR conducted a "Footprint" investigation to assess the environmental conditions directly under the concrete footprint of the MOSF Complexes A and B. As part of this "Footprint" investigation, a surface soil assessment as well as deeper subsurface soils assessment was completed after the demolition of the tank complexes. Based on DEC DER-10 guidance, 42 sample locations were advanced during the 2012 "Footprint" Site Investigation. HDR also installed 9 temporary piezometers within the footprint of the former tank complexes to assess the groundwater conditions beneath the former tank farm. Five piezometers were installed in Complex A and 4 piezometers were installed in Complex B.

Results of the Footprint Investigation concluded that the Site soil consists of urban fill. Analytical data for VOCs, SVOCs, pesticides, Polychlorinated Biphenyls (PCBs) and metals were generally consistent with the chemical composition of urban fill or associated with creosote treated wood piles, which exist at Complex B only (concrete piles supported the Complex A tank farm). At the Site (Complex A), there appears to be two primary areas where elevated chemical constituent concentrations were detected. One area is at the southeast corner of the complex, near the intersection of North First Street and River Street.

In the southeast area of the Site, VOCs apparently have migrated from the Fyn Paint facility and impacted this area. Concentrations of ethylbenzene, toluene and total xylenes were detected in the double to triple digit milligram per kilogram (mg/kg)/part per million (ppm) range in the 2012 subsurface soil sample (FP A-3) collected at the water table in this area. Based on the results of the 2012 soil samples collected from the surrounding borings (FP A-2, FP A-4, and FP A-5), the impacted area did not appear to extend far onto the Site.

The second impacted area of the Site is near the East River, at the northwest corner of Complex A. This area appeared to be impacted by poly aromatic hydrocarbons (PAHs) as evidenced by certain SVOCs exceeding the Unrestricted Use SCOs in subsurface soil samples. A separate fill source from the remainder of Complex A was the suspected source as no other sample locations within Complex A had PAH concentrations on this order of magnitude. The investigation and results are documented in the Site Investigation Report, Second Phase, "Footprint Investigation", HDR, June 2012, which is included as Appendix B.

2 Parcel II Investigation

This Investigation was completed to supplement/update the "Footprint" Investigation for Complex A in 2012 and was conducted in accordance with the DEC-approved Work Plan, with the following two modifications:

- one additional (ninth) borehole and temporary well point was installed at the request of Con Edison.
- an additional Quality Assurance (QA) sample, a trip blank, was submitted for analyses to comply with the sample frequency stated in the work scope

Borehole and temporary monitoring piezometer locations are shown on Figure 3.

In addition to the approved work plan, the investigation was also completed in accordance with the site specific Health and Safety Plan (HASP), which was approved by Con Edison prior to the start of the field activities.

On July 23, 2015, a kick off meeting was held with representatives from Con Edison and HDR participating. During this meeting, nine borehole locations were identified and tentatively marked in the field with pin flags. These locations were considered tentative pending the results of a geophysical survey and subsurface utility clearance ("soft dig") activities associated with the site investigation.

The field activities consisted of three primary tasks:

- utility mark-out, survey and hand clearing;
- soil borings with sampling and temporary monitoring well installation; and
- groundwater sampling.

Each task is discussed below.

2.1 Utility Mark-Out and Soft Dig

Prior to the mobilization of drilling equipment, HDR contracted a private utility mark-out contractor, Diversified Geophysics (Diversified) of Mineola, New York, to mark out utilities and other potential underground anomalies within the work area. On July 28, 2015, Diversified mobilized to the Site to implement the geophysical investigation. Diversified employed ground penetrating radar (GPR) technology and a 3M Dynatel® 2250M-iD Cable/Pipe Locator to locate subsurface obstructions/anomalies. A series of parallel traverses, in both the north/south and east/west directions were established and detected targets were marked in the field using paint and or pin flags. Due to the presence of historic tank support piles in the areas near some proposed borehole locations, three boreholes were offset approximately 18 inches from their original locations to areas clear of the subsurface obstructions.

Other than concrete piles to support the former Tank Complex A (several of which were visible at ground surface, no subsurface anomalies were identified during the

geophysical survey. Therefore, a map showing the locations of the subsurface anomalies was not prepared.

As an added precaution and part of the Con Edison intrusive investigation program, the upper 5 feet of each soil boring was excavated using non-mechanical methods to confirm the absence of utilities (soft dig). Aquifer Drilling & Testing, Inc. (ADT) was contracted to provide soft dig services in advance of the drilling operations. Before intrusive work commenced, ADT initiated the One Call notification system as required by New York State Code Rule 753-3.2. ADT's hand clearing crew mobilized to the Site on July 30, 2015 to clear 9 borehole locations using vacuum and hand dig techniques prior to intrusive activities. Each location was cleared to a depth of five feet below ground surface (bgs) with the exception of two borehole locations, PZ A-07 ALT and PZ A-11 (Figure 3). Soft digging at PZ A-07 ALT was terminated at 4.4 feet bgs when the water table was encountered, while clearance activities at PZ A-11 met refusal at 3.7 feet bgs on subsurface construction and demolition debris. Additional attempts at clearing these locations were not pursued, with Con Edison concurrence.

During soft digging intrusive activities, HDR screened the headspace above the excavation to monitor for organic vapors using a Rae Systems MultiRae 2000 photoionization detector (PID) with a 10.6 eV lamp. Elevated PID readings were not detected during the soft digging operation, with the exception of monitoring the headspace at PZ A-06. This location is near the southeast corner of the Site, where VOC impacts were previously identified.

Soils were classified during soft dig activities and recorded on boring logs (Appendix C). Typically, soils above the water table consisted of silty sands with varying amounts of brick, asphalt, concrete, gravel and cobbles. Upon completion of each borehole, each hole was backfilled with the cuttings removed from that location, including the material removed from the PZ A-06 location as no PID readings or odors were noted in the top 5 feet. Each location was then marked with fluorescent green flagging for future borehole advancement/documentation of the location using Differential Global Positioning System (DGPS).

2.2 Soil Borings

On August 3 and 4, 2015, ADT mobilized a Geoprobe® 7720 track mounted direct push technology drill rig to the Site for the advancement of 9 boreholes (Figure 3) to characterize subsurface soil conditions and allow for the collection of soil samples for laboratory analysis. All borings were advanced continuously in five-foot increments using a 2-inch diameter Macrocore® barrel with dedicated PVC liners. Each borehole was advanced to 15 feet bgs, with the exception of PZ A-08 ALT, which meet refusal at 10 feet bgs.

An HDR environmental scientist was on-Site during the drilling activities to log soils and collect soil samples for laboratory analyses. Upon collection, samples were immediately screened with the PID to assess whether organic vapors were present. If organic vapors were noted, a sample of that interval representing a worst case situation could be collected for laboratory analyses. Soils from each boring were then described in accordance with the Unified Soil Classification System (USCS) for material type and composition, color, grain size and distribution, depth to water, visual or olfactory

evidence of contamination, as well as any other distinctive characteristics. This information was documented on boring logs which are included as Appendix C.

Subsurface material observed during the drilling operations were described as fine to medium sands with varying amounts of silts, clays and debris such as brick, concrete coal, ash, wood and glass. Approximate depths to groundwater ranged from 5.5 to 8 feet bgs.

Soil cuttings generated during the subsurface investigation were containerized in a DOT approved 55-gallon drum and staged on site for waste characterization sampling and subsequent off-site disposal. On August 4, 2015, soil cuttings were sampled for waste characterization parameters. Results of the waste characterization were forwarded to Con Edison on September 14, 2015 and the waste was removed by Con Edison on September 21, 2015 for subsequent disposal.

2.2.1 Soil Sampling and Analysis

As part of this Site investigation, 9 subsurface soil samples were collected. One sample from each boring was retained from either the depth which exhibited the highest PID reading or the interval directly above the water table. Soils for analysis were transferred from dedicated PVC liners directly into laboratory provided glassware. Each container was then labeled with the appropriate sample identification number and sample depth, the analytical parameters to be analyzed, the date and time of sampling, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier. Soil samples submitted to the laboratory were analyzed for VOCs using EPA Method 8260C. Additionally, quality assurance/quality control (QA/QC) samples including field blanks (1 per day), trip blanks (1 per sample shipment), and duplicates (1 per 20 samples collected) were collected and submitted for laboratory analysis of VOCs using EPA Method 8260C.

Due to a laboratory provided courier error, three samples were analyzed outside of holding times. One sample was less than 1 hour out of holding time and the two other samples were about 10 and 11 hours outside hold times. Samples were maintained at the appropriate temperature despite the lab error so the analytical results are not expected to be compromised.

Upon completion of each borehole, all sampling equipment (e.g., Macrocore® sampler) was decontaminated with an Alconox and tap water wash, followed by a de-ionized or distilled water rinse. Drill cuttings were placed in a DOT-rated drum for subsequent waste characterization sampling and off Site disposal. Soil from one borehole (PZ A-06) showed evidence of a potential impact with a heavy sheen and elevated PID readings noted on the soils.

2.3 Temporary Piezometer Installation

Upon reaching the termination depth for each borehole, a 10 foot length of 1 inch diameter polyvinyl chloride (PVC), 0.002 inch slot screen coupled to a PVC riser section was placed in the borehole such that the screened section of each piezometer

intersected the groundwater table and the finished height of each well was 2-3 feet above the ground surface. The annular space around the well was backfilled with well-grade type sand to a minimum of two feet above the well screen. The space above the sand pack was completed with a bentonite seal. Each piezometer was finished off with a compression fit plug. Piezometer construction logs documenting the construction details are included as Appendix D. Locations of the piezometers are shown on Figure 3.

Following installation, the nine temporary piezometers were developed on August 5, 2015, using a peristaltic pump with dedicated tubing. During development, the piezometers were periodically surged in an attempt to remove fine grained sediments that may have been entrained within the borehole. During purging, the discharge water was periodically screened using a turbidity meter. Well development for each well continued until the water was less than 50 nephelometric turbidity units (NTUs) or for duration of one hour, whichever occurred first. Development water was containerized and staged in DOT-rated 55 gallon drums on-Site for future characterization and off-site disposal.

2.3.1 Groundwater Sampling and Analysis

Upon completion of groundwater gauging, one groundwater sample was collected from each of the nine piezometers. Sampling occurred on August 26 and 27, 2015. Dedicated ¼-inch, inside diameter (ID) low density polyethylene (LDPE) tubing was placed into each temporary piezometer and connected to a variable speed peristaltic pump utilizing laboratory-grade silicone tubing. HDR sampled the newly installed piezometer via EPA Region II low flow sampling methods with one modification: turbidity was considered stable at three consecutive readings within 10 percent deviation *or three consecutive readings below 10 NTUs*. Well Sampling logs are included as Appendix E.

Once stable conditions were reached, groundwater samples were collected and placed directly into laboratory supplied glassware. Each container was then labeled with the appropriate sample identification number, parameters to be analyzed, date and time, as well as the field personnel who collected the samples. Sample containers were then placed in a cooler with ice and sent under chain of custody protocol to TestAmerica, Inc., in Shelton, CT, a NYSDOH certified laboratory, via laboratory-provided courier.

Purged water was collected in a five gallon pail and subsequently transferred into DOT-rated 55 gallon drums with the well development water. Following groundwater sampling, a waste classification sample of the development and purge water was collected and submitted to TestAmerica for analyses. Waste characterization samples were collected on August 27, 2015.

All groundwater samples were analyzed for VOCs using EPA Method 8260C, chloride, and salinity. QA/QC sampling including field blanks (1 per day), trip blanks (1 per sample shipment) and a duplicates (1 per 20 samples) were also collected for VOCs and sent to TestAmerica for analysis.

3 Analytical Results

3.1 Soil

Analytical results of the samples collected during this Investigation were compared to NYSDEC Part 375 Soil Cleanup Objectives (SCOs) for Restricted Residential Use and Protection of Groundwater. Based on the laboratory analytical results of the 9 samples, the soils across the Site generally appear consistent. However, exceedances of certain potential future use SCOs are reported.

A summary of the analytical results is included as Table 1 and on Figure 4. The laboratory analytical data package is provided as Appendix F.

One sample, PZ A-06 (6') was reported to have concentrations above the Part 375 Restricted Residential Use and Protection of Groundwater SCOs. Concentrations of three compounds, ethylbenzene (22 mg/kg), total xylene (135 mg/kg), and toluene (2.3 mg/kg) exceeded the Protection of Groundwater Use SCOs of 1 mg/kg, 1.6 mg/kg, and 0.7 mg/kg, respectively for this sample. Total xylene (135 mg/kg) was the only VOC detected at a concentration that exceeded the Restricted Residential Use SCOs. The total xylene concentration of 135 mg/kg detected in the soils at the PZ A-06 location was above the Restricted Residential SCO of 100 mg/kg. The ethylbenzene, total xylenes, and toluene concentrations detected at this location are likely attributable to contamination migrating from the Fyn Paint facility to the east.

With one exception, no other compounds were detected in any other borings in excess of the Restricted Residential or Protection of Groundwater SCOs. Acetone was detected in the PZ A-09 (6.5) Dup sample at 0.098 mg/kg. The Protection of Groundwater SCO for acetone is 0.05 mg/kg. However, acetone was detected in the parent sample, PZ A-09 (6.5') at 0.019 mg/kg, which is below the Protection of Groundwater and Restricted Residential Use SCOs.

3.2 Groundwater

To assess groundwater quality and further delineate the impacted groundwater at Parcel II, 9 temporary piezometers were installed for groundwater sampling. A summary of the analytical data is included as Table 2. Analytical data packages are provided as Appendix F. Figure 5 shows the analytical data associated with the sample locations.

Analytical results show that 10 VOCs were detected in Site groundwater above applicable TOGS 1.1.1 GWQS or guidance values. Cis 1,2-dichloroethene, vinyl chloride, 1,1-Dichloroethane, isopropylbenzene, trichloroethene, methyl tert butyl ether (MTBE), benzene, ethylbenzene, total xylenes and toluene were the VOCs detected above the GWQS or guidance values at Parcel II. Toluene, ethylbenzene, and total xylenes were detected in concentrations that are four orders of magnitude above the GWQS and guidance values. These VOCs are typically not indicative of No. 6 fuel oil, especially at these concentrations. The origin of these compounds is likely associated with the Fyn Paint and Lacquer site, which is upgradient of Parcel II. During the Fyn

Paint investigations, elevated concentrations of these compounds were detected in a source area with downgradient sample results showing lesser concentrations, indicating migration to the west towards Parcel II.

Vinyl chloride was detected at four piezometer locations (PZ A-12 Alt, PZ A-11, PZ A-08 Alt, and PZ A-06). Concentrations of vinyl chloride ranged from 2 to 10 ug/l, which is the same order to one order of magnitude above the TOGs 1.1.1 Standard of 2 ug/l. Cis-1,2-dicholorethene was detected at two piezometer locations (PZ A-12 Alt and PZ A-11) with concentrations reported as 8 and 13 ug/l respectively, which is on the same order to one order of magnitude above the TOGS standard of 5 ug/l. Trichloroethene (16 ug/l), was detected in one well (PZ A-11) at a concentration one order of magnitude above the TOGS Standard of 5 ug/l. The source of cis-1,2-dichloroethene, vinyl chloride, 1,1-dichloroethane and trichloroethene is not known. These compounds are associated with perchloroethene decomposition and are not associated with No. 6 fuel oil.

The only other compound that was detected during groundwater sampling of the newly installed piezometers was MTBE. MTBE was detected at 18 ug/l, which is on the same order of magnitude as the TOGS 1.1.1 standard of 10 ug/l. The origin of the MTBE is unknown. MTBE is associated with gasoline and not associated with No. 6 fuel oil.

Chloride concentrations ranged from 190,000 ug/l in the PZ A-06 sample to 500,000 ug/l in the PZ A-09 sample. The distribution of chloride concentrations is not indicative of salt water intrusion unless preferential pathways through the fill exist. However, the concentrations of several samples are above the TOGS guidance value of 250,000 ug/l.

Salinity was not detected in any of the nine groundwater samples at detection limits of 2 parts per thousand (ppth). Salinity levels in sea water are consistent at 35 ppth (Vernier Software & Technology). Therefore, it does not appear the eastern portion of Parcel II is affected by salt water intrusion.

4 Summary

Based on a comparison of the recent groundwater data with the 2012 “Foot Print” Investigation of Complex A, the subsurface conditions appear to be unchanged. Contaminants of concern and concentrations detected in 2015 are generally consistent with the 2012 data. Concentrations detected near the southeast corner of Parcel II (PZ A-06) were lower than the concentrations detected in 2012 (Sample PZ-A-1), but were on the same order of magnitude. Acetone was detected in the central portion of Parcel II during the 2012 investigation but was below detection limits for groundwater samples in 2015.

In summary, consistent with the 2012 investigation, the data obtained during this investigation confirm historic operations at the Fyn Paint facility have impacted the southeastern corner of the Parcel II property with dissolved phased VOCs. Based on this investigation, the horizontal extent of the impact is confirmed to be limited to the southeast corner of Parcel II.

APPENDIX G: Qualifications of Environmental Professionals

RESUME

DAVID C. PULVERMILLER
PROJECT MANAGER

PROFESSIONAL EDUCATION

Bachelor of Arts, Environmental Science, State University of New York at Plattsburgh - 1988

CERTIFICATIONS / QUALIFICATIONS

- New York State Asbestos Inspector
- NRPP Residential Measurement Provider
- Certified Home Inspector, InterNACHI
- Lead Awareness Training
- HUD PCNA Training - Addressing Accessibility in Capital Needs Assessments
- Termites and Other Wood Destroying Pests Training
- HAZWOPER Training with Annual Refresher

SELECTED EXPERIENCE

Mr. Pulvermiller brings over twenty-three years of experience with a diverse technical background that has focused on environmental project management to Nova Consulting Group. As an Environmental Professional, he has completed over 1,000 Phase I Environmental Site Assessments (ESAs), numerous soil and groundwater studies, and remediation projects throughout the northeast.

PHASE I ENVIRONMENTAL SITE ASSESSMENTS AND PROPERTY CONDITIONS ASSESSMENTS

Mr. Pulvermiller has conducted Phase I and II Environmental Assessments, remedial investigations and cleanups, and Property Condition Assessments in 15 states across the country for REITs, CMBS lenders, banks, developers and other forms of lenders, government agencies and investors nationwide. Property types inspected range from high-rise towers, office buildings, shopping centers, hotels, apartment buildings, warehouses, industrial manufacturing facilities, and storage facilities. Reports were prepared for the following clients and protocols: JP Morgan, Home Loan and Investment Bank, Ridgewood Savings Bank, North Fork Bank, Union Savings Bank, Merrill Lynch, Bear Stearns, Prudential Mortgage Capital Company, First Union Bank, Washington Mutual, and numerous others. Currently he is part of the management team in the New York office to provide a full range of real estate due diligence service including PCA's, Phase I & II environmental reports and asbestos surveys.

SITE EVALUATION AND REMEDIATION

Mr. Pulvermiller has served as a project manager and field operations supervisor for many large-scale remediation projects including soil removal and disposal prior to the construction of the 101 Avenue of the Americas office building in Manhattan, New York. Operated as a Health and Safety Officer during a portion of the PCB remediation project at the SUNY New Paltz, New York campus.

Since 1993, Mr. Pulvermiller has been a vice president for a company on Long Island, New York and owned his own firm for a number of years prior to joining Nova. These firms specialized in the preparation of Phase I and II Environmental Site Assessments, soil and groundwater investigations and remediation, asbestos surveys, and UST removals for various lending institutions, developers, and other investors nationwide. Additionally, he has extensive experience with bringing properties into compliance with federal and state regulatory agencies including the USEPA, NYSDEC, NJDEP, and CTDEP.

DEANNA LEE, EP
SENIOR PROJECT MANAGER

PROFESSIONAL EDUCATION

Bachelor of Science, Chemical Engineering, Chung-Ang University, Seoul, South Korea, 2001

CERTIFICATIONS / QUALIFICATIONS

- Environmental Professional (EP) in accordance with ASTM E1527-13
- California Asbestos Building Inspector, #21056
- Phase I Environmental Site Assessment Experience, 14+ years
- OSHA 40 Hour Hazardous Waste Operations Certification (29CFR 1910.120)
- Termite and Wood Destroying Pests Training
- AARST/NRPP Certified Radon Measurement Provider

SELECTED EXPERIENCE

Ms. Lee is an Environmental Professional with more than ten years of experience in environmental consulting industry. Her experience includes the organization and project management of Phase I Environmental Site Assessments (ESAs) on various types of properties including vacant land, multi-family residential properties, hotels, offices, retail shopping center, mobile home parks, auto repair facilities, warehouses, and industrial facilities, supervising of Phase II Investigation including dry cleaning operations, gasoline service stations, and industrial properties, third party consultation on behalf of public and private clients with regard to contaminated sites and adjacent contaminated sites, and communicating with regulatory agencies in most of City and County of California.

Ms. Lee has conducted over 1,000 ESAs in accordance with ASTM E1527, the EPA All Appropriate Inquiry rule, and Freddie/Fannie including several ARCO Shell, Chevron branded gasoline service stations and advised the clients including lenders, developers, and real estate investors throughout her career.

Ms. Lee conducted a Phase I ESA of a 5-acre truck terminal with a truck maintenance facility located in the City of South Gate, California. This facility historically maintained two underground storage tanks and clarifiers which were removed from the property. The fill material was identified within the southern portion of the property in late 1940s and 1950s. Also, this site was associated with an incomplete investigation with the Los Angeles County Department of Public Works (LACDPW) and identified as a potential candidate for a Preliminary Assessment with United States Environmental Protection Agency (USEPA). Ms. Lee's investigation recommended a Phase II investigation in connection with the onsite fill material and the incomplete investigation with the LACDPW.

Ms. Lee conducted a Phase I ESA for a vacant lot located in the City of El Monte, California. The northern portion of this property was located within a National Priority Lists (NPL) area with groundwater and soil contamination with various volatile organic compounds (VOCs), trichloroethylene (TCE), and tetrachloroethylene (PCE) and this property was a probable location of a closed illegal landfill operated by CalTrans from 1960 until 1977. Ms. Lee managed a Phase II investigation including soil and soil vapor sampling at this property.

RAYMOND H. HUTCHISON
VICE PRESIDENT

PROFESSIONAL EDUCATION

Bachelor of Science, Environmental Science, William Paterson College, Wayne, NJ, 1994

CERTIFICATIONS/QUALIFICATIONS

- New York State Department of Labor, Asbestos Project Designer
- New York State Department of Labor, Asbestos Management Planner
- New York State Department of Labor, Project Monitor
- New York City Department of Environmental Protection, Asbestos Investigator
- New Jersey Department of Environmental Protection, Licensed Subsurface Evaluator
- Certified Environmental Inspector
- 40-Hour OSHA Hazard Materials Worker and Technician
- 24 Hour OSHA Health and Safety Course
- AHERA/ New York State Department of Labor, Asbestos Inspector
- California Environmental Protection Agency - Registered Environmental Assess

CREDENTIALS

- School of Continuing and Professional Studies – Certificate in Real Estate Finance and Investment
- Environmental and Occupational Health Sciences Institute, New Jersey Asbestos Safety Technician Course
- GE Capital Services, Center for Learning & Organizational Excellence - Supplier Champions Training
- Rutgers University, Cooks College School of Continuing Education - Technical and Regulatory Training in Underground Storage Tanks,
- Rutgers University, Cooks College School of Continuing Education - Surface/Groundwater and Soil Field Sampling
- NYU, School of Continuing Education - Phase I Environmental Assessment and NYSDOH Asbestos Investigations

EXPERIENCE

Mr. Hutchison has over seventeen years of experience in the engineering and environmental science fields. His experience involves Phase I Environmental Site Assessments, lead-based paint surveys, radon testing, and drinking water surveys of various real estate including premium class hotels, various mid-sized and large-sized mall facilities, apartment complexes, commercial offices, retail buildings, nursing home facilities, and industrial facilities. He has been personally involved in the details of thousands of real estate transactions for various client types and therefore understands the specific needs and scopes of work required for the different parties involved in the transaction. He is familiar with the due diligence requirements of a varied number of reporting standards, including the new standard ASTM E1527-05, EPA's All Appropriate Inquiry (AAI), Fannie Mae DUS, and Freddie Mac. He also has experience with fulfilling numerous customized client scopes of work. His due diligence resume includes experience at all levels including advising lenders, real estate investors, and other client types through the following product types: Phase I

Environmental Site Assessments, Environmental Transaction Screens, Phase II Subsurface Investigations, Remedial Cost Estimates, Remediation Design, Property Condition Assessments, Probable Maximum Loss Assessments, Preliminary Endangerment Assessments, Lead-Based Paint Surveys, Asbestos Surveys and Asbestos Abatement.

He has experience reviewing thousands of Phase I Environmental Site Assessments, Phase II Subsurface Investigations, Property Condition Assessments and Asbestos Surveys for others.

His Phase II experience includes soil sampling, groundwater sampling, installation of groundwater monitoring wells, underground storage tank testing and removal, and dry-cleaner subsurface evaluations. Additional previous environmental experience includes conducting technical reviews of air permit applications and underground storage tank applications and performing regulation compliance inspections at manufacturing facilities.

He also has experience conducting asbestos surveys, asbestos abatement design and monitoring, preparation of technical specifications and general conditions of contracts for asbestos abatement projects and preparation of regulatory documentation of asbestos investigations. He has been the point person for many asbestos abatement projects; his responsibilities included negotiating bids and hiring contractors, executing contracts, creating and implementing protocol, developing client-specific report templates, supervising inspectors and monitors, and reviewing subcontractor logs and documentation.

He has assisted clients on over 15,000 commercial real estate transactions throughout his career. His due diligence experience encompasses all levels, including, but not limited to, advising lenders, REITS, developers, property managers, attorneys, and real estate investors through every aspect of the real estate transaction throughout the United States and Europe. He has provided coordination and review of property assessments for many portfolios for both private equity owners and major financial institutions. The reviews presented the current conditions at the properties, costs to address deficiencies and costs to address future capital replacements.

Other major projects include large-scale loan portfolios, due diligence assessments encompassing equity level Property Condition Assessments, which have included projects requiring aggregation of specialty service scopes within the realm of building sciences. His collective experience in the field of real estate due diligence has enabled him to support property owners, prospective purchasers, and clients' legal counsel through numerous successful transactions of major New York City landmark buildings.
